Supporting Information Placeholder

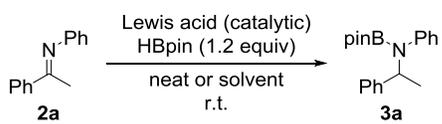

ABSTRACT: The rarely used boron Lewis acid tris[3,5-bis(trifluoromethyl)phenyl]borane (BAR^F₃) is found to be an excellent catalyst for metal-free hydroboration of imines. In the presence of 1.0 mol % of BAR^F₃, several ketimines and aldimines undergo hydroboration with pinacolborane (HBpin) at room temperature without the aid of an external Lewis base. BAR^F₃ is more reactive than other Lewis-acidic boranes, including often-used tris(pentafluorophenyl)borane [B(C₆F₅)₃]. The steric hindrance imparted by the six fluorine atoms *ortho* to the boron center in B(C₆F₅)₃ accounts for this. Mechanistic control experiments indicate conventional Lewis-acid catalysis involving imine activation and hydride transfer from HBpin.

Catalytic imine hydroboration is a straightforward way of preparing ubiquitous amines.¹ However, the number of protocols, of which the majority makes use of transition metals as catalysts, is still limited,² and imine hydroboration relying on main-group elements as catalysts is currently attracting attention.³ In 2012, Crudden and co-workers reported a metal-free imine hydroboration at room temperature where the actual catalyst **1** is generated from the combination of B(C₆F₅)₃ or [Ph₃C]⁺[B(C₆F₅)₄]⁻, DABCO (1,4-diazabicyclo[2.2.2]octane), and pinacolborane (HBpin). Hence, this transformation is initiated by B(C₆F₅)₃ or the trityl cation but catalyzed by the borenium ion **1** (Scheme 1, top).⁴ We recently found that tris[3,5-bis(trifluoromethyl)phenyl]borane (BAR^F₃)⁵ promotes the hydroboration of alkenes with HBpin while tris(pentafluorophenyl)borane [B(C₆F₅)₃] does not.⁶ Detailed mechanistic studies unveiled electron-deficient Ar^F-substituted hydroboranes generated by substituent redistribution between BAR^F₃ and HBpin are the real catalysts. Herein, we disclose that BAR^F₃ is also competent to catalyze the hydroboration of imines with HBpin at room temperature without the assistance of an external Lewis base (Scheme 1, bottom).

Scheme 1. Imine Hydroboration at Room Temperature Catalyzed by Boron Lewis Acids

We began investigating this imine hydroboration using ketimine **2a** as the model substrate (Table 1). No reaction was observed after 18 h at room temperature without a catalyst (entry 1). We then tested different boron Lewis acids. Triphenylborane (BPh₃) was not sufficiently Lewis acidic (entry 2). Similar to Crudden's findings,⁴ strongly Lewis-acidic B(C₆F₅)₃ showed poor catalytic activity, furnishing 36% conversion after 18 h (entry 3). In stark contrast, BAR^F₃ cleanly led to quantitative conversion of the imine to the amine (entry 4). Lowering the catalyst loading from 2.0 to 0.30 mol % was not detrimental, again providing full conversion (entry 5). We note here that [Ph₃C]⁺[B(C₆F₅)₄]⁻ did not react at all (entry 6). Also, HB(C₆F₅)₂, known as Piers' borane, showed hardly any conversion (entry 7)⁷ while HBAR^F₂·SMe₂ performed as efficiently as BAR^F₃ (entry 8 vs entry 3).⁸ Using 1.0 mol % of BAR^F₃ as catalyst, we compared the reaction rates in several solvents at 1 h reaction time (entries 9–13). Benzene emerged as best, affording 58% conversion (entry 9); full consumption of the imine was obtained after 18 h, and the free amine was isolated in 87% yield after hydrolysis (entry 14). For the sake of completeness, B(C₆F₅)₃ was also probed in benzene yet without any improvement over the neat reaction, even with 5.0 mol % (entry 15 vs entry 3).—Although the present study is about the striking reactivity difference between BAR^F₃ and B(C₆F₅)₃, we nevertheless tried BCl₃ and BF₃·OEt₂ as catalysts in benzene as the solvent (entries 16 and 17). With 20 mol % catalyst loading, BCl₃ still performed poorly but BF₃·OEt₂ was able to mediate the imine hydroboration with quantitative conversion.

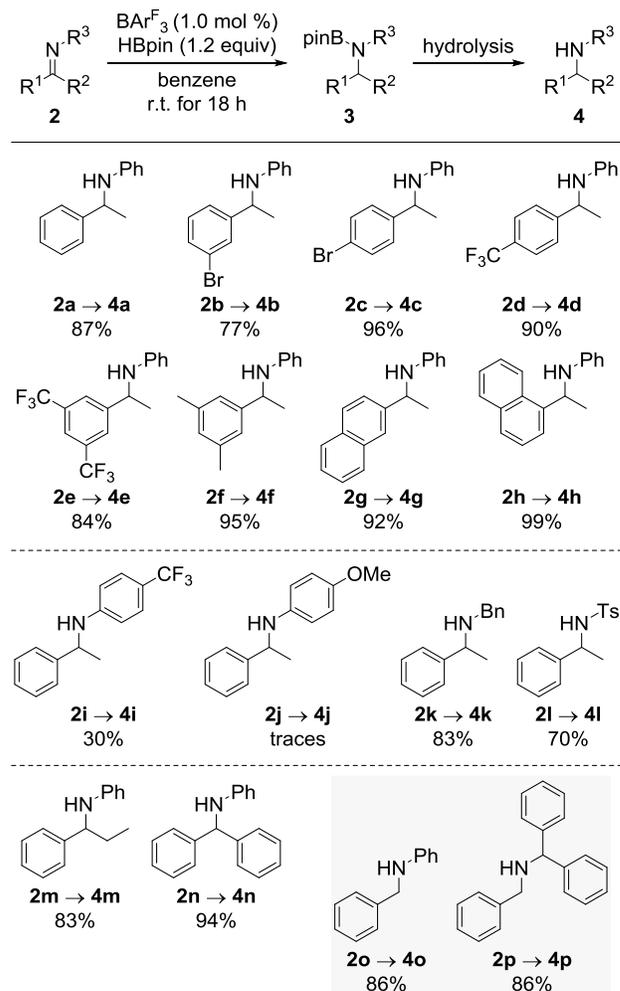

Table 1. Optimization of the Catalytic Imine Hydroboration^a

entry	Lewis acid	mol %	time (h)	solvent	conv ^b (%) ^c
1	—	—	18	neat	0
2	BPh ₃	2.0	18	neat	0
3	B(C ₆ F ₅) ₃	2.0	18	neat	36
4	BAR ^F ₃	2.0	18	neat	100
5	BAR ^F ₃	0.30	18	neat	100
6	[Ph ₃ C] ⁺ [B(C ₆ F ₅) ₄] ⁻	10	18	neat	0
7	HB(C ₆ F ₅) ₂	3.0	18	neat	5
8	HBAR ^F ₂ ·SMe ₂	3.0	18	neat	100
9	BAR ^F ₃	1.0	1	benzene	58
10	BAR ^F ₃	1.0	1	toluene	30
11	BAR ^F ₃	1.0	1	PhCF ₃	37
12	BAR ^F ₃	1.0	1	CH ₂ Cl ₂	34
13	BAR ^F ₃	1.0	1	1,2-Cl ₂ C ₂ H ₄	37
14	BAR ^F ₃	1.0	18	benzene	100 (87) ^c
15	B(C ₆ F ₅) ₃	5.0	6	benzene	<5
16	BCl ₃	20	18	benzene	27
17	BF ₃ ·OEt ₂	20	18	benzene	99

^aAll reactions were performed on a 0.1 mmol scale either neat or in solvent (1 M) in a sealed tube. ^bDetermined by GLC analysis using tetracosane as internal standard. ^cIsolated yield of the free amine after hydrolysis and purification by flash chromatography on silica gel.

With the optimal conditions in hand, we assessed the scope of this hydroboration reaction (Scheme 2). Various N-phenyl-protected ketimines **2a–h** with either electron-withdrawing (Br and CF₃) or -donating groups (Me) on the benzene ring were tested. Full conversion was observed throughout, giving the corresponding amines **4a–h** in 77 to 99% yield after aqueous workup. We then investigated the effect of different protecting groups on the nitrogen atom. A CF₃ substituent in the *para* position of the phenyl group (as in **2i**) resulted in a dramatic decrease of substrate reactivity while a MeO substituent in the same position (as in **2j**) completely thwarted the reaction. Changing of the protecting group from phenyl to benzyl (as in **2k**) or tosyl (as in **2l**) did not bring about any significant reactivity difference and good yields were obtained in both cases. Moreover, ketimines **2m** and **2n** derived from α -methyl acetophenone and benzophenone, respectively, were also suitable

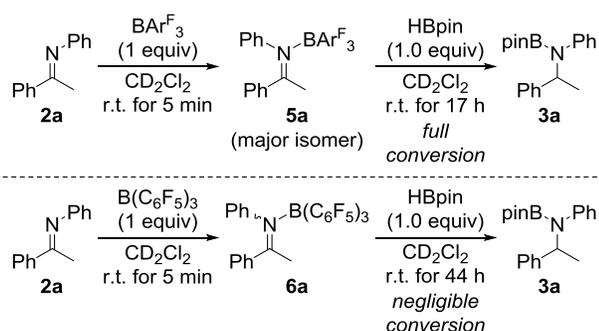

substrates. Finally, aldimines **2o** and **2p** also proved to be good substrates, both undergoing the hydroboration in 86% yield (gray box).

Scheme 2. BAR^F₃-Catalyzed Hydroboration of Ketimines and Aldimines

To gain insight into the mechanism of this facile imine hydroboration, several stoichiometric control experiments were performed. No interaction between the model ketimine **2a** and HBpin was observed by ¹H and ¹¹B NMR spectroscopy when mixing equimolar amounts of these reactants in CD₂Cl₂ (see the Supporting Information for details). Equimolar amounts of **2a** and BAR^F₃ immediately formed the expected Lewis pair **5a** in CD₂Cl₂; **5a** was assigned to be the thermodynamically more stable isomer by multinuclear NMR measurements.⁹ Subsequent treatment of **5a** with stoichiometric HBpin resulted in smooth reduction, and full conversion was reached after 17 h (Scheme 3, top). Notably, the catalyst BAR^F₃ precipitated from the solution after completion of the reaction. In-situ formation of hydroboranes [H_nBAR^F_{3-n}]₂ (*n* = 1 and 2) as well as [(Ar^F)₂(H)B(μ -H)₂BAR^F₂] as potential catalysts (cf. Table 1, entry 8) from ligand exchange between BAR^F₃ and HBpin was not observed.⁶ Importantly, the diagnostic formation of Ar^F-Bpin was not detected in both the stoichiometric and the catalytic setups. This stands in contrast to our previous study of alkene hydroboration where that substituent redistribution occurs.⁶ We believe that the σ -basic imine as opposed to the π -basic alkene prevents that process because of its better coordi-

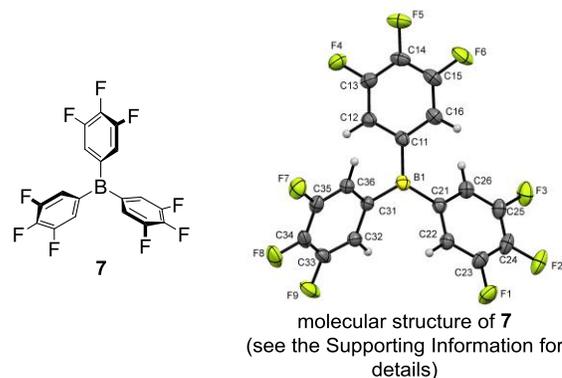

nating ability. Furthermore, neither the formation of any borenium or boronium ions nor the presence of hydridoborate [HBAr^{F_3}] $^-$ as the counteranion was seen in the NMR spectra. This essentially excludes the possibility of borenium-ion catalysis (cf. Scheme 1, top).^{4,10} Directly mixing **2a**, HBpin, and BAr^{F_3} in CD_2Cl_2 had the same outcome. For comparison, we repeated the same experiment with $\text{B}(\text{C}_6\text{F}_5)_3$ where rapid formation of the expected Lewis adduct **6a** was also found. However, **6a** was reluctant to react with HBpin, and only traces of reduction were observed after 44 h (Scheme 3, bottom).— Competition experiments in CD_2Cl_2 (treatment of **5a** with $\text{B}(\text{C}_6\text{F}_5)_3$ and **6a** with BAr^{F_3} , respectively) revealed that the formation of **6a** is strongly favored over **5a**. It must be noted though that the solubility of BAr^{F_3} is rather poor, potentially shifting the equilibrium toward **6a**.

Scheme 3. Stoichiometric Control Experiments: BAr^{F_3} Against $\text{B}(\text{C}_6\text{F}_5)_3$

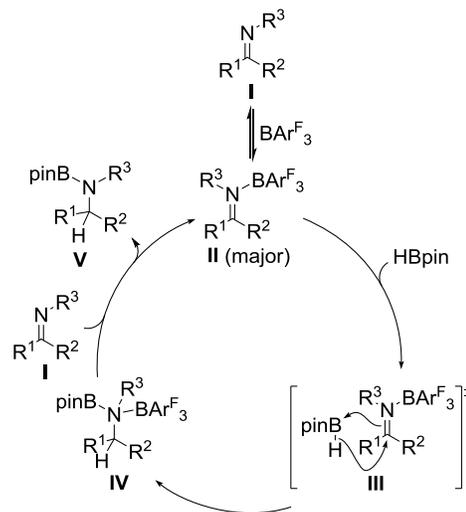

According to literature data,^{5a} the Lewis acidities of BAr^{F_3} and $\text{B}(\text{C}_6\text{F}_5)_3$ are quite similar, depending on the Lewis base and, hence, on the relative Lewis-acidity scale. We therefore thought that the big difference in catalytic activity between the two could be ascribed to steric effects. $\text{B}(\text{C}_6\text{F}_5)_3$ with its six *ortho* fluorine atoms in the proximity of the boron center is far more sterically hindered than BAr^{F_3} . To support this hypothesis, we prepared tris(3,4,5-trifluorophenyl)borane (**7**)¹¹ devoid of *ortho* substitution (Scheme 4, top). In line with our assumption, this borane exhibited excellent activity in catalytic imine hydroboration, and full conversion was achieved after 4 h at room temperature (not shown). A control experiment with stoichiometric formation of the Lewis adduct analogous to those outlined above (cf. **2a** \rightarrow **5a** or **6a** \rightarrow **3a**, Scheme 3) confirmed this result (**2a** \rightarrow **8a** \rightarrow **3a**, Scheme 4, bottom).

Scheme 4. Molecular Structure of Tris(3,4,5-trifluorophenyl)borane and Stoichiometric Control Experiment

Based on literature precedence¹² and consistent with our experimental observation, we postulate the following mechanism for the BAr^{F_3} -catalyzed imine hydroboration (Scheme 5). BAr^{F_3} coordinates to the imine nitrogen atom, thereby lowering the LUMO of the imine (**I** \rightarrow **II**). Lewis adduct **II** is then reduced to **IV** by HBpin, likely through transition state **III** (**II** \rightarrow **III** \rightarrow **IV**). Transfer of BAr^{F_3} from Lewis adduct **IV** to the more Lewis-basic imine **I** eventually furnishes the N-borylated amine **V** and closes the catalytic cycle (**IV** \rightarrow **V**).

Scheme 5. Postulated Catalytic Cycle for Imine Hydroboration

In conclusion, the strong boron Lewis acids BAr^{F_3} as well as tris(3,4,5-trifluorophenyl)borane have been uncovered as efficient catalysts for imine hydroboration. Unlike the previous report by Cruden and co-workers,⁴ the new protocol did not require the aid of an external Lewis base. A conventional mechanism for Lewis-acid catalysis was shown to be operative. Control experiments corroborated that the steric hindrance imparted by the *ortho* fluorine atoms in $\text{B}(\text{C}_6\text{F}_5)_3$ accounts for

the enormous reactivity difference between BAr^{F}_3 and widely used $\text{B}(\text{C}_6\text{F}_5)_3$. The present work is another example of a catalysis where $\text{B}(\text{C}_6\text{F}_5)_3$ fails to react effectively.⁶

- (10) Unlike Crudden's initiation of the borenium-ion catalysis with $[\text{Ph}_3\text{C}]^+[\text{B}(\text{C}_6\text{F}_5)_4]^-$ in the presence of DABCO,⁴ absolutely no reduction occurs with catalytic (see Table 1, entry 6) as well as stoichiometric amounts of the trityl cation in the absence of Lewis bases other than the imine. Instead, imine dimerization through trityl-cation-mediated enamine formation was obtained from an equimolar combination of the three reactants dissolved in CD_2Cl_2 while HBpin remained untouched; HBpin was found to be degraded by stoichiometric treatment with $[\text{Ph}_3\text{C}]^+[\text{B}(\text{C}_6\text{F}_5)_4]^-$ in independent experiments in CD_2Cl_2 or C_6D_6 .
- (11) $\text{Tris}(3,4,5\text{-trifluorophenyl})\text{borane}$ (7) was prepared by treatment of 3,4,5-trifluorophenyllithium with $\text{BF}_3\cdot\text{OEt}_2$ at -78°C ; the pure borane was obtained after 2-fold sublimation (see the Supporting Information for details).
