The halodecarboxylation of heteroarene carboxylic acids by treatment with N-bromosuccinimide or N-chlorosuccinimide was performed. This procedure provides a convenient route to synthetically useful mono-halogenated heteroarene intermediates such as halo-indoles, -aza-indoles, -indazoles and -aza-indazoles. The mild conditions employed and simple protocol provides an advantage over traditional halodecarboxylation procedures that require expensive and toxic metal catalysts, basic conditions, time-consuming intermediate isolation and elevated reaction temperatures.

1. Introduction

Haloheteroarenes serve as versatile building blocks in organic chemistry, most notably as coupling partners in transition metal-catalysed cross-coupling reactions for the formation of C–C and C–N bonds. Owing to their utility, haloheteroarenes have been used in the construction of molecules of biological interest including natural products [1–3] and small molecules in drug discovery programmes such as Merck’s recent LRRK2 inhibitor, MLi-2 [4] and Vertex’s PKC θ inhibitor (figure 1) [5].

Few methods are documented that describe the selective monohalogenation of heteroaromatic scaffolds [6–8]. A traditional approach to the regiospecific installation of a halogen atom on a substrate is the thermal halodecarboxylation of a silver(I) carboxylate salt in the presence of a halide source known as the Hunsdiecker–Borodin reaction (HBR) (figure 2) [10–12].

Figure 2. Strategies for halodecarboxylation [8,9].
Substrates for the HBR are often aliphatic carboxylates with limited aromatic and heteroaromatic carboxylates being employed successfully [9]. The preparation of bromopyridazines under basic aqueous conditions at elevated temperatures offers a rare example of the HBR being successfully applied to heterocyclic acid substrates [13,14]. The major shortcoming of the HBR is the requirement to isolate the dry silver carboxylate salt in sufficient purity to undergo decarboxylation and afford the corresponding halide in good yield [15]. Accordingly, modifications of the HBR such as the Cristol–Firth modification (CFM) and Kochi modification (KM) avoid the need to isolate the silver salt by employing more stable metal salts such as red mercury [16] and lead acetate [17] that undergo halodecarboxylation on heating in situ. The CFM and KM suffer from the same major limitation that they both employ toxic metal reagents to initiate the decarboxylation. The Barton modification avoids the use of toxic and expensive metals yet requires the preparation of the respective thiohydroxamate ester (Barton ester). Halodecarboxylation of the Barton ester results in the formation of both the desired halide and the undesired 2-(alkylthio)-pyridine side-product, limiting the atom efficiency of the reaction (figure 2) [18]. Recent advances in the field include the metal-free decarboxylative halogenation of unsaturated carboxylic acids with N-halosuccinimides in the presence of tetrabutylammonium trifluoroacetate [19], LiOAc [20] or photolysis with bromine and PhI(OAc)2 [21,22]. Hypervalent iodine has also been used by Hamamoto & Miki [23] for the synthesis of polybromindoles. However, this methodology is seemingly unable to produce mono-halogenated products and requires the use of alkali metal salts as the halide source. Since preparing this manuscript, a recent report by Larrosa [24] has described the decarboxylative iodination of benzoic and heterobenzoic acids through the use of iodine and potassium phosphate. Although this protocol is very diverse, it requires the use of stoichiometric amounts of base, elevated temperatures (100°C) and currently suffers from over bromination (when bromine is used in place of iodine) [10].

The 4, 6 and 7 positions on the indazole (products 3–5) underwent decarboxylative bromination in excellent yields with the bromodecarboxylation of indazole 1 with NBS. The reaction proceeded with two equivalents of NBS in N,N-dimethylformamide (DMF) at room temperature affording product 2 in 35% yield (table 1, entry 1) after just 1 h. Inspection of the reaction mixture by liquid chromatography-mass spectrometry (LCMS) analysis appeared to show that a dibrominated product had also formed as a major impurity. Gratifyingly, by decreasing the equivalents of NBS it was observed that no measurable amount of dibrominated product was formed. Despite the reaction being facile it was found that by extending the reaction time from 1 to 16 h, the reaction reliably went to completion. Under the optimized conditions product 2 was furnished in 77% isolated yield (table 1, entry 2).

Reactions involving NBS can be exothermic and can pose a risk when undertaken on a large scale [25], therefore, we sought to employ a solvent that was predicted to be safe to use on a large scale and in addition would furnish the desired product in high yield. A small solvent screen was undertaken with solvents that were reported to cause negligible exotherms when used with NBS (table 1, entries 3–5) [25]. Unfortunately, none of these solvents facilitated the halodecarboxylation reaction in as high yield as observed when the reaction was carried out in DMF (table 1).

With the halodecarboxylation procedure in hand, the indazole carboxylic acid scope was investigated (figure 3). A variety of indazole carboxylic acids were subjected to the reaction with NBS in DMF (products 2–13). Examples of indazole acids bearing electron withdrawing (products 3–5) and electron donating substituents (products 8 and 9) underwent decarboxylative bromination in excellent yields under the reaction conditions. However, when the electron donating methoxy group was moved to the 4, 6 and 7 positions on the indazole (10, 11 and 12), no product could be detected. The use of N-methyindazole to afford compound 13 appeared to be unsuccessful, with no halodecarboxylated products.

We now turned our attention to chlorodecarboxylation and iododecarboxylation reactions using the optimized conditions but employing NCS and N-iodosuccinimide (NIS) as halide sources (table 2, entries 2 and 3). Although the chlorodecarboxylation product (table 2, entry 2) was obtained in lower yield than the bromodecarboxylation product (table 2, entry 1) using similar conditions, the current procedure...

Figure 4. Halodecarboxylation of heteroarene carboxylic acids. Reaction conditions: heteroarene carboxylic acid (0.2 mmol), NBS (0.2 mmol), solvent (1.5 ml) at room temperature (rt).

represents one of the few ways to synthesize chloroheteroarenes under mild conditions. Unfortunately, the iododecarboxylation was not facilitated under the current reaction conditions.

To demonstrate the versatility of the halodecarboxylation procedure for heteroarenes, further reactions with NBS were investigated (figure 4). Although halo-indoles (products 14–16) have been reported in the literature to be problematic to isolate [26,27], under the current procedure we have been able to furnish 15 and 16 in reasonable yields.

Aza-indole and aza-indazole acids underwent halodecarboxylation smoothly to furnish the corresponding haloheteroarenes 17 and 18 in good yield, implying that more electron deficient systems undergo halodecarboxylation efficiently under the current conditions. Attempts to further expand this methodology to simple benzoic acids have currently proved unsuccessful, although this remains an active area of research within our group.

3. Conclusion

In summary, a mild and efficient protocol for the mono-halodecarboxylation of heteroarene carboxylic acids has been developed. It is noteworthy that this halodecarboxylation is metal-free and displays significant advantages over traditional methods of halodecarboxylation that commonly require harsh reaction conditions, toxic reagents or suffer over bromination. The proposed method extends the substrate scope of traditional halodecarboxylations to heteroarene substrates. This methodology
provides a novel and direct route to haloheteroarene building blocks that can be used in transition metal-catalysed cross-coupling reactions to construct molecules of scientific importance. Investigations into the site-selective halodecarboxylation of other heteroarene acid precursors are currently underway in our laboratory.
