Abstract: The detection of (structural) breaks or the so called change point problem has drawn increasing attention from the theoretical, applied economic and financial fields. Much of the existing research concentrates on the detection of change points and asymptotic properties of their estimators in panels when \( N \), the number of panels, as well as \( T \), the number of observations in each panel are large. In this paper we pursue a different approach, i.e., we consider the asymptotic properties when \( N \to \infty \) while keeping \( T \) fixed. This situation is typically related to large (firm-level) data containing financial information about an immense number of firms/stocks across a limited number of years/quarters/months. We propose a general approach for testing for break(s) in this setup. In particular, we obtain the asymptotic behavior of test statistics. We also propose a wild bootstrap procedure that could be used to generate the critical values of the test statistics. The theoretical approach is supplemented by numerous simulations and by an empirical illustration. We demonstrate that the testing procedure works well in the framework of the four factors CAPM model. In particular, we estimate the breaks in the monthly returns of US mutual funds during the period January 2006 to February 2010 which covers the subprime crises.

JEL classification codes: C10, C23, C33.

Key words: Change point problem; stationarity; panel data; bootstrap; four factor CAPM model; US mutual funds.

1. Introduction

Structural changes and model stability in panel data are of general concern in empirical economics and finance research. Model parameters are assumed to be stable over time if there is no reason to believe otherwise. It is well-known that various economic and political events can cause structural breaks in financial data. Such events include, for example, the change of parameters associated with the introduction of a single currency in Europe, price liberalization in emerging markets, and world integration of equity markets. Further examples and discussions can be found in Hansen (2001), Andreou and Ghysels (2009) among others. The exact time of change is usually unknown and therefore the construction of tests for stability is a challenging question. Andrews (1993) (cf. corrigendum Andrews, 2003) provides the first econometric insights into break detection. Brodsky and Darkhovskii (2000) and Csörgő and Horváth (1997) cover the early development from statistical point of view.

In both the statistics and econometrics literature we can find very many of papers related to the detection of changes and structural breaks. Recent developments in the field consider a general class of time series processes and panel data models with errors that can exhibit temporal dependence, heteroskedasticity, trending variables, possible unit roots, cointegration and long memory processes. For a literature survey we refer the reader to Arellano (2004), Perron (2006) and Aue and Horváth (2012).

A model for panel data with possible breaks in the mean was introduced by Joseph and Wolfson (1992, 1993). Bai (2010) significantly generalized the earlier results, still assuming that the panels are independent of each other, thanks to allowing serial correlation within each panel. This approach was extended by Horváth and Hušková (2012), who discussed dependence between the panels via common factors. Results on breaks in the means and/or in the variances have been extended to various forms of linear regression by Kim (2011), Baltagi et al. (2016) and Kao et al. (2012, 2014), among others.

Existing research mostly concentrates on testing for structural breaks in the panel data when $T$, the number of observations in each panel, goes to infinity and $N$, the number of panels/firms/assets/individuals, also goes to infinity, but slower than $N$ (Bai, 2010, Bai and Carrion-i-Silvestre, 2009, Kim, 2011, Baltagi at al., 2016).

In this paper we study a different asymptotic case when $T$ is finite and $N$ goes to infinity. This situation is typically related to large firm-level data panels containing financial information about a very substantial number of firms/stocks across a limited number of years/quarters. The issue of model stability in such a setup applies to broadly defined research in empirical asset pricing as well as in corporate finance. For example, asset pricing models hinge heavily on the stability of factor parameters to explain stock returns, while the financial industry eyes the generation of alpha returns (Fama and French, 1993 and 2014, Ghysels, 1998, Guercio and Reuter, 2014).

Similarly, in corporate finance the leverage literature relies on several parameters to estimate target leverage ratios, and on the stability of fixed effects to show persistence in capital structure choices (DeAngelo and Roll, 2015, Lemmon at al., 2008). Pešta and Peštová (2015) use this setup for an application to insurance mathematics, while Torgovitski (2015) focuses on multiple changes in spatial functional data. Cho and Fryzlewicz (2015) and Jirák (2015) study estimates and tests for multiple change points in high dimensional data.

There is evidence of structural breaks in the financial market that affect financial indicators, including returns and volatility, changes in exchange rate regimes, asset allocations, equity premium, value at risk (VaR), expected shortfall (ES), credit risk models,
etc. Recently, researchers have started to analyze structural breaks in the panel data setup, which reveal an increasing variety of potential applications with a strong impact in financial economics (cf., for example DeAngelo and Roll, 2015, Graham et al, 2015, Whited and Wu, 2006). Hence the stability of parameter estimates in panel data, and the estimation of the time of change where \( T \) is fixed and \( N \) goes to infinity have interesting applications.

In this paper we consider the model

\[(1.1) \quad y_{i,t} = x_{i,t}^\top (\beta_i + \delta I\{t \geq t_0\}) + e_{i,t}, \quad 1 \leq i \leq N \text{ and } 1 \leq t \leq T,\]

where \( x_{i,t} = (x_{i,t}(1), \ldots, x_{i,t}(d))^\top \) are vectors of explanatory variables (design points that can be random or non-random), \( \beta_i \in \mathbb{R}^d \) are unknown regression (vector) parameters in the \( i \)th panel and \( ^\top \) denotes the transpose of vectors and matrices. Finally, we assume that \( e_{i,t} \) are errors that can be cross-sectionally correlated. As previously mentioned, we consider the detection of the unknown time of change. The regression parameters in the \( i \)th panel change from \( \beta_i \) to \( \beta_i + \delta_i \) at unknown time \( t_0 \), usually called either a change point or a break point.

The paper is structured as follows. Section 2 introduces our notation, settings and lists the main assumptions. Section 3 contains the main results (detailed proofs are provided in the technical appendix). Section 4 describes the (wild) bootstrap procedure for one of the proposed test statistics. We use Monte Carlo simulations to illustrate the finite sample properties of the test. Section 5 contains an application to real data. Finally, Section 6 concludes the paper. Proofs are presented in Section 7.

2. Notation, settings and general assumptions

First we introduce some notation that will be used through the paper. Since we are dealing with detection and estimation of an unknown change point, we will analyze various estimators, matrices, and parameters before and after a certain time \( t \), \( 1 \leq t \leq T \).

In particular, \( \hat{\beta}_{i,t} \) and \( \tilde{\beta}_{i,t} \) denote the OLS estimators computed from the first \( t \) and the last \( T - t \) observations of the \( i \)th panel, respectively. Hence,

\[(2.1) \quad \hat{\beta}_{i,t} = (X_{i,t}^\top X_{i,t})^{-1} X_{i,t}^\top Y_{i,t}, \quad t_1 \leq t \leq T,\]

\[(2.2) \quad \tilde{\beta}_{i,t} = (\tilde{X}_{i,t}^\top \tilde{X}_{i,t})^{-1} \tilde{X}_{i,t}^\top \tilde{Y}_{i,t}, \quad 1 \leq t \leq T - t_2,\]

where \( Y_{i,t} = (y_{i,1}, y_{i,2}, \ldots, y_{i,t})^\top \), \( \tilde{Y}_{i,t} = (y_{i,t+1}, y_{i,t+2}, \ldots, y_{i,T})^\top \),

\[
X_{i,t} = \begin{pmatrix} x_{i,1}(1), x_{i,1}(2), \ldots, x_{i,1}(d) \\
 x_{i,2}(1), x_{i,2}(2), \ldots, x_{i,2}(d) \\
 \vdots \\
x_{i,t}(1), x_{i,t}(2), \ldots, x_{i,t}(d) \end{pmatrix} = \begin{pmatrix} x_{i,1}^\top \\
x_{i,2}^\top \\
\vdots \\
x_{i,t}^\top \end{pmatrix}
\]

and

\[
\tilde{X}_{i,t} = \begin{pmatrix} x_{i,t+1}(1), x_{i,t+1}(2), \ldots, x_{i,t+1}(d) \\
x_{i,t+2}(1), x_{i,t+2}(2), \ldots, x_{i,t+2}(d) \\
\vdots \\
x_{i,T}(1), x_{i,T}(2), \ldots, x_{i,T}(d) \end{pmatrix} = \begin{pmatrix} x_{i,t+1}^\top \\
x_{i,t+2}^\top \\
\vdots \\
x_{i,T}^\top \end{pmatrix}.
\]
We also denote by “tr” the trace of a matrix and put
\[ Z_{i,t} = X_{i,t}^\top X_{i,t}, \quad \tilde{Z}_{i,t} = \tilde{X}_{i,t}^\top \tilde{X}_{i,t}, \quad t = 1, \ldots, T. \]

2.1. Test statistics. We propose several test statistics for the change point problem in the panel data when \( T \) is fixed and \( N \to \infty \). We are interested in testing if there is a change in the regression parameters. We introduce two processes and their functionals can be used as test statistics.

Under the null hypothesis there is no change in the coefficients, i.e., the null hypothesis is stated as
\[
H_0 : \sum_{i=1}^{N} \| \delta_i \| = 0,
\]
where \( \| \cdot \| \) denotes the Euclidean norm vectors and matrices.

We consider two types of test procedures; the first is based on quadratic forms of least squares estimators and the second employs sums of squares of residuals. First, let us consider
\[
(2.4) \quad U_N(t) = \sum_{i=1}^{N} (\beta_{i,t} - \hat{\beta}_{i,T})^\top C_{i,t}(\beta_{i,t} - \hat{\beta}_{i,T}), \quad \max\{d, t_1\} \leq t \leq \min\{T - d, T - t_2\}.
\]

\( U_N(t) \) is a Wald-type test statistic (with weighting matrices \( C_{i,t} \)'s) for each \( t \) to compare the least squares estimators computed from the first \( t \) observations with the estimator from the full sample. To keep the detection procedure broad we do not restrict \( C_{i,t} \) to a particular form. Instead we list a set of assumptions that \( C_{i,t} \) should satisfy and we will discuss pros and cons of particular choices of \( C_{i,t} \) later.

The second test procedure is based on the process
\[
(2.5) \quad V_N(t) = \sum_{i=1}^{N} \sum_{s=1}^{t} \tilde{e}_{i,s}^2, \quad \tilde{e}_{i,s} = y_{i,s} - x_{i,s}^\top \hat{\beta}_{i,T}, \quad 1 \leq i \leq N, \ 1 \leq t \leq T,
\]
representing CUSUM-type statistics based on partial sums of the squares of the residuals.

In general, large values of \( U_N(t) \) and/or \( V_N(t) \) for at least some \( t \) indicate that the null hypothesis is violated. Required critical values can be obtained either asymptotically or through a proper version of the bootstrap.

2.2. Assumptions. This subsection contains a set of assumptions needed to prove the main theorems describing asymptotic properties of the suggested test statistics. We start with assumptions about the error terms and assume that they can be decomposed as
\[
(2.6) \quad \varepsilon_{i,t} = \gamma_i^\top \Lambda_t + \varepsilon_{i,t},
\]
where \( \Lambda_t \in R^k, 1 \leq t \leq T \) is the common factor, \( \varepsilon_{i,t}, 1 \leq i \leq N, 1 \leq t \leq T \) are the innovations and \( \gamma_i \in R^q, 1 \leq i \leq N \), is loading in the \( i^{th} \) panel satisfying:

Assumption 2.1. \( E \Lambda_t = 0 \) and \( E \| \Lambda_t \| ^2 < \infty, 1 \leq t \leq T \).

Assumption 2.2. \( \quad (i) \ The \ innovations \ \varepsilon_i = (\varepsilon_{i,1}, \varepsilon_{i,2}, \ldots, \varepsilon_{i,T})^\top, \ i = 1, \ldots, N \ are \ independent; \)
\( (ii) \ E \varepsilon_{i,t} = 0, \ E \varepsilon_{i,t} \varepsilon_{i,s} = 0 \) and \( c_3 \leq \sigma_i^2 = E \varepsilon_{i,t}^2 \leq c_4 \) for all \( 1 \leq i \leq N, 1 \leq t \neq s \leq T \) with some constants \( 0 < c_3 \leq c_4 < \infty \);
there is \( \kappa > 4 \) such that \( \limsup_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E|\varepsilon_{i,t}|^\kappa < \infty, \ 1 \leq t \leq T \).

Note that Assumption 2.2 (ii) is usually satisfied in financial applications, since ARCH, GARCH and similar volatility models assume uncorrelated innovations (cf. Francq and Zakoian (2010)).

**Assumption 2.3.** \( \{A_t, 1 \leq t \leq T\} \) and \( \{\varepsilon_i, 1 \leq i \leq N\} \) are independent.

Let us note that serial correlation of the error disturbances in the original model (1.1) can be obtained via common factors defined in error term decomposition (2.6). The serial correlation observed in \( e_{i,t} \) can then be viewed as impure correlation caused by omitting common factors in the main regression model (1.1).

**Assumption 2.4.**

\[
\lim_{N \to \infty} \frac{1}{N^{1/2}} \sum_{i=1}^{N} \|\gamma_i\|^2 = 0.
\]

As usual we assume that the common factors are negligible. Inference with non-negligible common factors in change-point detection has been mentioned by several authors in different setups when both \( N \) and \( T \) go to infinity but \( N \) is much smaller than \( T \) (cf. Horváth and Hušková, 2012 and Baltagi et al., 2016). We discuss the behavior of \( U_N(t) \) and \( V_N(t) \) when Assumption 2.4 fails in Section 3.4.

Now we continue with assumptions on the design matrix.

**Assumption 2.5.** There is \( c_0 \) such that \( \|x_{i,t}\| \leq c_0 \) for all \( 1 \leq i \leq N, \ 1 \leq t \leq T \).

**Assumption 2.6.**

(i) There are positive constants \( t_1 \) and \( c_1 \) such that \( (\sum_{j=1}^{t_1} x_{i,j}x_{i,j}^\top)^{-1} \) exists and \( \| (\sum_{j=1}^{t_1} x_{i,j}x_{i,j}^\top)^{-1} \| \leq c_1 \) for all \( i, \ 1 \leq i \leq N \);

(ii) there are positive constants \( t_2 \) and \( c_2 \) such that \( (\sum_{j=T-t_2}^{T} x_{i,j}x_{i,j}^\top)^{-1} \) exists and \( \| (\sum_{j=T-t_2}^{T} x_{i,j}x_{i,j}^\top)^{-1} \| \leq c_2 \) for all \( i, \ 1 \leq i \leq N \).

Notice that Assumption 2.6 (i) implies \( \| (\sum_{j=1}^{t} x_{i,j}x_{i,j}^\top)^{-1} \| \leq c_1 \) for all \( t \geq t_1 \) and that similarly to Assumption 2.6 (ii) we find that \( \| (\sum_{j=t+1}^{T} x_{i,j}x_{i,j}^\top)^{-1} \| \leq c_2 \) for all \( t \leq T - t_2 \). Assumption 2.6 (i) guaranties that the OLS estimators in (2.1) and (2.2) are uniquely defined.

For the sake of simplicity we assume that the \( x_{i,t} \)'s are non-random. We briefly discuss modifications of Assumptions 2.5 and 2.6 to allow random design vectors in Section 3.5.

Finally, we present our assumptions on weighting matrices.

**Assumption 2.7.** \( C_{i,t} = C_{i,t}^\top \), it is non-negative definite for all \( 1 \leq i \leq N, d \leq t \leq T - d \), and there exist constants \( c_5 \) and \( t_3, t_4 \) such that \( \|C_{i,t}\| \leq c_5 \) for all \( 1 \leq i \leq N, t_3 \leq t \leq T - t_4 \).

Instead of a particular choice of weighting matrices, we consider a general condition which would guarantee the validity of theorems and testing procedures specified later. Nevertheless, by a specific choice of \( C_{i,t} \) we can obtain variants/generalizations of standard tests. In particular, by choosing

\[
C_{i,t} = Z_{i,t}^{-1} \tilde{Z}_{i,t} D_{i,t} \tilde{Z}_{i,t}^{-1}
\]
where \( D_{i,t} \) are positive semidefinite matrices and \( \tilde{\beta}_{i,t} \) and \( \tilde{\beta}_{i,t} \) are defined by (2.1) and (2.2), we have that

\[
U_{1,N}(t) \equiv U_{1,N}(t; D_{i,t}) = U_N(t; Z_{i,T}^{-1} \tilde{Z}_{i,t} D_{i,t} \tilde{Z}_{i,t}^{-1}) = \sum_{i=1}^{N} (\tilde{\beta}_{i,t} - \bar{\beta}_{i,t})^\top D_{i,t} (\tilde{\beta}_{i,t} - \bar{\beta}_{i,t}).
\]

Another useful choice of the weighting matrices \( C_{i,t} \) is \( C_{i,t} = Z_{i,t} G_{i,t} Z_{i,t} \) gives

\[
U_{2,N}(t) = U_N(t; Z_{i,t} G_{i,t} Z_{i,t}) = \sum_{i=1}^{N} \left( \sum_{v=1}^{t} x_{i,v} (y_{i,v} - x_{i,v}^\top \tilde{\beta}_{i,T}) \right)^\top G_{i,t} \left( \sum_{v=1}^{t} x_{i,v} (y_{i,v} - x_{i,v}^\top \tilde{\beta}_{i,T}) \right),
\]

where \( G_{i,t} \) is a positive semidefinite weighting matrix.

We note that \( U_{2,N}(t) \) requires only the existence of \( Z_{i,t}^{-1} \). Also, \( U_{2,N}(t) \) can be interpreted as a weighted version of \( V_N(t) \).

3. Main Results

3.1. Results under \( H_0 \). First we present the main results on the limit behavior of \( U_N(t) \) and \( V_N(t) \) under the null hypothesis.

Define

\[
a_{i,t,1}^2 = \sigma_i^2 \left( \sum_{s=1}^{t} x_{i,s}^\top (Z_{i,t}^{-1} - Z_{i,t}^{-1}) C_{i,t} (Z_{i,t}^{-1} - Z_{i,t}^{-1}) x_{i,s} + \sum_{s=t+1}^{T} x_{i,s}^\top Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1} x_{i,s} \right)
= \sigma_i^2 \left\{ \text{tr} \left((Z_{i,t}^{-1} - Z_{i,t}^{-1}) C_{i,t} (Z_{i,t}^{-1} - Z_{i,t}^{-1}) Z_{i,t}^{-1} \right) + \text{tr} \left(Z_{i,T}^{-1} C_{i,t} Z_{i,t}^{-1} \tilde{Z}_{i,t}^{-1} \right) \right\}
= \sigma_i^2 \text{tr} \left(C_{i,t} (Z_{i,t}^{-1} - Z_{i,t}^{-1}) \right),
\]

\[
A^{(1)}_N(t) = \sum_{1 \leq i \leq N} a_{i,t,1}^2,
\]

\[
a_{i,t,2}^2 = \sigma_i^2 \sum_{s=1}^{t} \left( 1 - x_{i,s}^\top Z_{i,t}^{-1} x_{i,s} \right) = \sigma_i^2 \left( t - \text{tr} \left(Z_{i,t}^{-1} \right) \right), \quad A^{(2)}_N(t) = \sum_{i=1}^{N} a_{i,t,2}^2,
\]

\[
S_{i,t} = \sum_{s=1}^{t} x_{i,s} e_{i,s}.
\]

To state the asymptotic distributions of \( U_N(t) \) and \( V_N(t) \) we need the existence of their asymptotic covariance functions. This is specified in Assumptions 3.1 and 3.2.

**Assumption 3.1.** The function

\[
\Gamma^{(1)}(t, t') = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \left[ E \left\{ (Z_{i,t}^{-1} S_{i,t} - Z_{i,t}^{-1} S_{i,t})^\top C_{i,t} (Z_{i,t}^{-1} S_{i,t} - Z_{i,t}^{-1} S_{i,t}) \times (Z_{i,t'}^{-1} S_{i,t'} - Z_{i,t'}^{-1} S_{i,t'})^\top C_{i,t'} (Z_{i,t'}^{-1} S_{i,t'} - Z_{i,t'}^{-1} S_{i,t'}) \right\} - a_{i,t,1}^2 a_{i,t,1}'^2 \right]
\]
exists for all \( t, t' \leq T - \bar{t}_0 \), where \( \bar{t}_0 = \max(d, t_1, t_3) \) and \( \bar{t}_0 = \max(d, t_2, t_4) \).

**Assumption 3.2.** The function

\[
\Gamma^{(2)}(t, t') = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \left[ \sum_{t'=1}^{T} \sum_{s'=1}^{\ell} E \left\{ (\varepsilon_{i,s} - x_{i,s}^T Z_{i,T}^{-1} s_{i,T}) (\varepsilon_{i,s'} - x_{i,s'}^T Z_{i,T}^{-1} s_{i,T}) \right\}^2 - a_{i,t',2}^2 \right]
\]

exists for all \( 1 \leq t, t' \leq T \).

Using these assumptions, we can state two theorems on asymptotic distribution of the test statistics \( U_N(t) \) and \( V_N(t) \) under the null hypothesis.

**Theorem 3.1.** If \( H_0 \), Assumptions 2.1–2.7 and 3.1 hold, then we have that, as \( N \to \infty \),

\[
\left\{ N^{-1/2} \left( U_N(t) - A_N^{(1)}(t) \right) \right\}, \quad \underline{L}_0 \leq t \leq T - \bar{t}_0 \xrightarrow{D} \left\{ \xi_t^{(1)}, \underline{L}_0 \leq t \leq T - \bar{t}_0 \right\},
\]

where \( \xi_t^{(1)}, \underline{L}_0 \leq t \leq T - \bar{t}_0 \), is jointly normal with zero mean, covariance \( \Gamma^{(1)}(t, t') \) and \( \underline{L}_0, \bar{t}_0 \) are defined in Assumption 3.1.

**Theorem 3.2.** If \( H_0 \), Assumptions 2.1–2.6 and 3.2 hold, then we have that, as \( N \to \infty \),

\[
\left\{ N^{-1/2} \left( V_N(t) - A_N^{(2)}(t) \right) \right\}, \quad 1 \leq t \leq T \xrightarrow{D} \left\{ \xi_t^{(2)}, 1 \leq t \leq T \right\},
\]

where \( \xi_t^{(2)}, 1 \leq t \leq T \), is jointly normal with zero mean and covariance \( \Gamma^{(2)}(t, t') \) defined in Assumption 3.2.

Proofs of both theorems are given in Section 7.

Theorem 3.1 and Theorem 3.2 can be used to find the asymptotic distributions of the test statistics based on \( U_N(t) \) and \( V_N(t) \) when \( H_0 \) holds.

3.2. **Results under alternatives.** We briefly discuss the behavior of the proposed test statistics when a change occurs. We focus on the statistics based on \( U_N(t) \), \( \underline{L}_0 \leq t \leq \bar{t}_0 \), since the behavior of tests based on \( V_N(t) \), \( 1 \leq t \leq T \), is similar.

We obtain asymptotically consistent tests of rejecting \( H_0 \) for large values of \( N^{-1/2} \max_i |U_N(t) - A_N^{(1)}(t)| \), if some of the changes \( \delta_i \)'s, the sizes of the changes, are sufficiently large. Particularly, if Assumptions 2.1–2.7 are satisfied and for some \( \underline{L}_0 \leq t, t_1 \leq T - \bar{t}_0 \)

\[
\frac{1}{\sqrt{N}} \sum_{i=1}^{N} \delta_i \left( Z_{i,t_1}(Z_{i,max(t_1,t)}^{-1} - Z_{i,T}^{-1})C_{i,t}(Z_{i,max(t_1,t)} - Z_{i,T}^{-1})Z_{i,t_1} \right) \delta_i \to \infty
\]

then we have that

\[
N^{-1/2} \max_i |U_N(t) - A_N^{(1)}(t)| \to P \infty,
\]

which together with Theorem 3.1 ensures asymptotic consistency of the test. One can show that (3.9) holds under other type of alternatives including multiple changes, gradual changes, or when larger changes occur only in a fraction of panels.

To find an estimator for \( t_0 \) we choose \( C_{i,t} \) such that for all \( t \) and \( i \)

\[
Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1} = G_T
\]
with some positive definite matrix $G_T$. Then under the alternative hypothesis the behavior of $|U_N(t) - A^{(1)}_N(t)|$ is asymptotically equivalent with

$$\frac{1}{\sqrt{N}} \sum_{i=1}^{N} \delta_i^T \left( Z_{i,l_0} Z_{i,T}^{-1} Z_{i,i} G T \tilde{Z}_{i,i} Z_{i,T}^{-1} \right) \delta_i, \quad t \geq t_0,$$

$$\frac{1}{\sqrt{N}} \sum_{i=1}^{N} \delta_i^T \left( \tilde{Z}_{i,l_0} Z_{i,T}^{-1} Z_{i,i} G T \tilde{Z}_{i,i} Z_{i,T}^{-1} \right) \delta_i, \quad t \leq t_0.$$

Note that the elements of the sums defined above are non-decreasing for $t \leq t_0$, while they are non-increasing for $t \geq t_0$. Then the condition for the asymptotic consistency (3.8) can be replaced by

$$\frac{1}{\sqrt{N}} \sum_{i=1}^{N} \delta_i^T \left( Z_{i,l_0} Z_{i,T}^{-1} Z_{i,i} G T \tilde{Z}_{i,i} Z_{i,T}^{-1} \right) \delta_i \to \infty,$$

and an estimator $\hat{t}_N$ of $t_0$ can be defined as

$$\hat{t}_N = \arg\max_{t=d,...,T-d} \left| U_N(t) - A^{(1)}_N(t) \right|.$$

The asymptotic properties of $\hat{t}_N$, as $N \to \infty$, are the subject of future research.

3.3. Remarks. The test procedures studied in the previous section depend on some unknown quantities. We briefly discuss their possible estimators.

The normalizing sequences $A^{(1)}_N(t)$ and $A^{(2)}_N(t)$ in Theorem 3.1 and 3.2 depend on the unknown variances $\sigma_i^2, i = 1, \ldots, N$. To estimate them we can employ the following options:

1. $\sigma_i^2$ is estimated by the sample variance of the $i^{th}$ panel

$$\hat{\sigma}_i^2 = \frac{1}{T - d} \sum_{t=1}^{T} \left( y_{i,t} - x_{i,t}^T \hat{\beta}_i \right)^2;$$

2. $\sigma_i^2$ is estimated by

$$\hat{\sigma}_i^2 = \min_{d \leq v \leq T - d} \frac{1}{T - 2d} \left\{ \sum_{t=1}^{v} \left( y_{i,t} - x_{i,t}^T \hat{\beta}_i \right)^2 + \sum_{t=v+1}^{T} \left( y_{i,t} - x_{i,t}^T \tilde{\beta}_i \right)^2 \right\}.$$

The estimator $\hat{\sigma}_i^2$ is asymptotically consistent under the one change point alternative. However, it is not stable since it includes $\hat{\beta}_i$ and $\tilde{\beta}_i$ when they are computed from a few observations. Hence in the simulations and the data example we use $\hat{\sigma}_i^2$.

The covariances $\Gamma^{(1)}$ and $\Gamma^{(2)}$ in Assumptions 3.1 and 3.2 are complicated functions of the observations. Nevertheless, they can be simplified for certain choices of the weighting matrices $C_{i,t}$ and moderate values of $T$. It follows from Assumptions 2.2 and 2.5 that

$$\frac{1}{N} \sum_{i=1}^{N} E \left\| \sum_{t=s}^{t} x_{i,v} \varepsilon_{i,v} \right\|^4 \leq c_{2,1} (t - s + 1)^2$$
and
\[
\left\| \sum_{i=s}^{t} x_{i,v} x_{i,v}^\top \right\| \leq c_{2,2}(t - s + 1)
\]
where \(c_{2,1}\) and \(c_{2,2}\) are some positive numbers. We note that if the \(x_{i,t}\)'s realizations of stationary, ergodic sequences with finite mean, then
\[
\frac{1}{T} Z_{i,T} \approx Z_i,
\]
assuming that \(Z_i\) is nonsingular, we arrive at the natural conclusion that
\[
\|Z_{i,T}^{-1}\| \leq c_{2,3}/T.
\]

Let us assume that \(C_{i,t} = Z_{i,t}^2\) in the definition of \(U_N(t)\). In this case
\[
\Gamma^{(1)}(t, t') = \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left\{ (S_{i,t} - Z_{i,t} Z_{i,t}^{-1} S_{i,T})^\top (S_{i,t} - Z_{i,t} Z_{i,t}^{-1} S_{i,T}) \right\}
\]
\[
\times (S_{i,t'} - Z_{i,t'} Z_{i,t'}^{-1} S_{i,T})^\top (S_{i,t'} - Z_{i,t'} Z_{i,t'}^{-1} S_{i,T}) - \sigma_{i,t}^2 \sigma_{i,t'}^2 \}
\]
and therefore by (3.12) and (3.13) we have for moderate and large \(T\)'s that
\[
\Gamma^{(1)}(t, t') \approx \lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} E \left\{ (S_{i,t} - t S_{i,T})^\top (S_{i,t} - t S_{i,T}) \right\}
\]
\[
\times (S_{i,t'} - t S_{i,T})^\top (S_{i,t'} - t S_{i,T}) - \sigma_{i,t}^2 \sigma_{i,t'}^2 \}
\]
The approximation for \(\Gamma^{(1)}(t, t')\) also shows that \(U_N(t)\) is related to CUSUM processes used extensively in change point analysis.

Under Assumption 2.4 (negligible influence of common factors) the residual \(\hat{\epsilon}_{i,t} = y_{i,t} - x_{i,t} \hat{\beta}_{i,T}\) is a good approximation for the innovation \(\epsilon_{i,t}\). Hence, under \(H_0\), we could use
\[
\hat{\Gamma}_N^{(1)}(t, t') = \frac{1}{N} \sum_{i=1}^{N} \left\{ \hat{S}_{i,t}^\top \hat{S}_{i,t} \hat{S}_{i,t'}^\top \hat{S}_{i,t'} - \hat{\sigma}_{i,t}^2 \hat{\sigma}_{i,t'}^2 \right\},
\]
where
\[
\hat{S}_{i,t} = \sum_{v=1}^{T} x_{i,v} \hat{\epsilon}_{i,v}, \quad \hat{\sigma}_{i,t,1}^2 = \hat{\sigma}_{i,t}^2 \text{tr} (Z_{i,t} Z_{i,t}^{-1} \bar{Z}_{i,t}) \quad \text{and} \quad \hat{\sigma}_{i,t}^2 = \frac{1}{T} \sum_{v=1}^{T} \hat{\epsilon}_{i,v}^2.
\]
to approximate the covariance matrix \(\Gamma^{(1)}(t, t')\), since \(\hat{S}_{i,T} = 0\).

In some models commonly used in econometric finance, e.g., CAPM type models, \(x_{i,t}\)'s do not depend on \(i\). The model and also the test statistics become much simpler, because the indices \(i\) in \(x_{i,t}\)'s and \(Z_{i,t}\)'s can be omitted and our weighting matrix also becomes independent on \(i\), i.e., \(C_{i,t} = C_t\), \(i = 1, \ldots, N\). Hence we have
\[
A_N^{(1)}(t) = \text{tr}(C_t (Z_t^{-1} - Z_T^{-1})) \sum_{i=1}^{N} \sigma_i^2 \quad \text{and} \quad A_N^{(2)}(t) = (t - \text{tr}(Z_t Z_T^{-1})) \sum_{i=1}^{N} \sigma_i^2.
\]
Then it suffices to estimate \( \sum_{i=1}^{N} \sigma_i^2 \) instead of a set of single \( \sigma_i^2 \)'s, \( i = 1, \ldots, N \).

### 3.4. Non-negligible common factors.

In this section we show that if Assumption 2.4 (negligible common factors) fails, then \( N^{-1/2}|U_N(t) - A_N^{(1)}(t)| \to \infty \) and \( N^{-1/2}|V_N(t) - A_N^{(2)}(t)| \to \infty \) in probability for some \( t \). These are immediate consequences of Theorem 3.3 and 3.4 stated below.

**Assumption 3.3.**

\[
\frac{1}{r_N} \sum_{i=1}^{N} \|\gamma_i\|^2 = O(1) \text{ with some numerical sequence satisfying } r_N/N^{1/2} \to \infty.
\]

**Assumption 3.4.** The limit

\[
Q(s, v, z) = \lim_{N \to \infty} \frac{1}{r_N} \sum_{i=1}^{N} \gamma_i x_i^\top \left( Z_i^{-1} - Z_i^{-1} \right) C_i x_i, 1 \leq s, v \leq z \leq T,
\]

exists and there are \( s_0, v_0 \) and \( z_0 \) such that \( 1 \leq s_0, v_0 \leq z_0 \leq T \), and at least one element of \( Q(s_0, v_0, z_0) \) is different from 0.

**Assumption 3.5.** The limit

\[
\overline{Q}(s, v, z) = \lim_{N \to \infty} \frac{1}{r_N} \sum_{i=1}^{N} \left( \frac{1}{T} \gamma_i - \gamma_i x_i^\top Z_i^{-1} x_i \right), 1 \leq s, v \leq z \leq T,
\]

exists, and there are \( s_0, v_0 \) and \( z_0 \) such that \( 1 \leq s_0, v_0 \leq z_0 \leq T \), and at least one element of \( \overline{Q}(s_0, v_0, z_0) \) is different from 0.

It follows from Assumption 3.3 that \( \|Q(s, v, z)\| < \infty \). Similarly, Assumption 3.5 implies that \( \|\overline{Q}(s, v, z)\| < \infty \). The rate \( r_N \) is the exact rate in Assumptions 3.3 and 3.4, i.e. the matrix \( Q \) is different from the zero matrix. The term describing the dependence between the panels dominates the limit since \( r_N/N^{1/2} \to \infty \).

**Theorem 3.3.** If \( H_0 \) and Assumptions 2.1–2.3, 2.5–2.7, 3.1 and 3.4 hold, then we have

\[
\left\{ \frac{1}{r_N} \left( U_N(t) - A_N^{(1)}(t) \right), L_0 \leq t \leq T - \bar{t}_0 \right\} \overset{D}{\to} \left\{ \xi_t^{(3)}, L_0 \leq t \leq T - \bar{t}_0 \right\}, \quad N \to \infty,
\]

where

\[
\xi_t^{(3)} = \sum_{s,v=1}^{t} A^\top s Q(s, v, t) A_v, \quad L_0 \leq t \leq T - \bar{t}_0,
\]

non-zero matrix \( Q \) is defined in Assumption (3.4) and \( L_0, \bar{t}_0 \) are defined in Assumption 3.1 and \( r_N \) in Assumption (3.3).

Now we formulate the analogue of Theorem 3.3 for \( V_N(t) \).

**Theorem 3.4.** If \( H_0 \) and Assumptions 2.1–2.3, 2.5–2.6 and 3.5 hold, then we have

\[
\left\{ \frac{1}{r_N} \left( V_N(t) - A_N^{(2)}(t) \right), 1 \leq t \leq T \right\} \overset{D}{\to} \left\{ \xi_t^{(4)}, 1 \leq t \leq T \right\}, \quad N \to \infty,
\]

where

\[
\xi_t^{(4)} = \sum_{s,v=1}^{t} A^\top s \overline{Q}(s, v, t) A_v, \quad 1 \leq t \leq T,
\]
and the non-zero matrix $Q$ is defined in Assumption 3.5.

Proofs of both theorems are given in Section 7.

Under the Assumptions of Theorems 3.3 and 3.4 the limit distributions are fully determined by the common factor $\Lambda_s$, $s \in T$, and are not normally distributed.

3.5. Random design vectors. For the sake of simplicity, Theorem 3.1 and 3.2 with their proofs are provided for non-random $x_{i,t}$'s. However, the results can be extended to random design points. We assume:

Assumption 3.6. $\{\varepsilon_{i,t}, 1 \leq i \leq N, 1 \leq t \leq T\}$ and $\{x_{i,t}, 1 \leq i \leq N, 1 \leq t \leq T\}$ are independent.

Assumptions 2.5 and 2.6 are modified so the uniform boundness is replaced with the uniform boundness of moments:

Assumption 3.7. There is $c_0$ such that $E||x_{i,t}||^8 \leq c_0$ for all $1 \leq i \leq N, 1 \leq t \leq T$ and

Assumption 3.8. (i) There are positive constants $c_1$ and $t_1$ such that $E||\sum_{t=1}^{t} x_{i,t}x_{i,t}^T||^8 \leq c_1$ for all $1 \leq i \leq N$.

(ii) There are positive constants $c_2$ and $t_2$ such that $E||\sum_{t=t_2}^{T} x_{i,t}x_{i,t}^T||^8 \leq c_2$ for all $1 \leq i \leq N$.

It follows from Assumption 3.8 that

$$P \left( \sum_{t=1}^{t} x_{i,t}x_{i,t}^T \right)^{-1} \text{ exists for all } t_1 \leq t \leq T = 1$$

and

$$P \left( \sum_{t=t_2}^{T} x_{i,t}x_{i,t}^T \right)^{-1} \text{ exists for all } t_2 \geq t = 1.$$  

We also need to replace $a_{i,t,1}^2$ and $a_{i,t,2}^2$, $1 \leq i \leq N, t_0 \leq t \leq T - \bar{t}_0$ with their expected values.

4. Bootstrap tests and simulations

4.1. Bootstrap tests. In this subsection we describe the settings of the wild bootstrap procedure that could be used to test for the change point.

Due to Assumption 2.4 (negligible common factors) we could also apply the bootstrap to get approximations to the distribution functions of $U_N(t)$ and $V_N(t)$. We demonstrate the application of the wild bootstrap for $U_N(t)$, and $V_N(t)$ can be resampled in a similar way.

For $t_0 \leq t \leq T - \bar{t}_0$ and $1 \leq i \leq N$ let

$$\phi_{i,t} = (\tilde{\beta}_{i,t} - \tilde{\beta}_{i,T})^\top C_{i,t} (\tilde{\beta}_{i,t} - \tilde{\beta}_{i,T}) - \frac{1}{N} \sum_{j=1}^{N} (\tilde{\beta}_{j,t} - \tilde{\beta}_{j,T})^\top C_{j,t} (\tilde{\beta}_{j,t} - \tilde{\beta}_{j,T}).$$

Assumption 4.1. $\zeta_1, \ldots, \zeta_N$ are independent standard normal variables, independent of $\{\varepsilon_{i,t}, 1 \leq i \leq N, 1 \leq t \leq T\}$
The bootstrapped observations are defined by
\[ \phi_{i,t}^* = \zeta_i \phi_{i,t}, \quad L_0 \leq t \leq T - \bar{t}_0, \quad 1 \leq i \leq N. \]
and the respective bootstrapped process by
\[ U_N^*(t) = N^{-1/2} \sum_{i=1}^{N} \phi_{i,t}^*, \quad L_0 \leq t \leq T - \bar{t}_0. \]

**Theorem 4.1.** We assume that Assumptions 2.6–3.1 and 4.1 hold.
(i) If \( H_0 \) holds, then
\[ \{U_N^*(t), L_0 \leq t \leq T - \bar{t}_0\} \xrightarrow{D} \{\xi^{(1)}_t, L_0 \leq t \leq T - \bar{t}_0\} \]
where \( \xi^{(1)}_t, L_0, \bar{t}_0 \) are defined in Theorem 3.1.
(ii) If \( H_A \) holds, then
\[ \sup_{L_0 \leq t \leq T - \bar{t}_0} |U_N^*(t)| = O_P(1). \]

**Proof:** See Section 7.

4.2. **Test procedure and algorithm.** Based on the results in the previous sections we describe here the test procedures for testing \( H_0 \) specified in (2.3) of our model (1.1). Our test procedures are based on the maximum functionals of

\[ \bar{U}_N(t) = N^{-1/2}(U_N(t) - A_N^{(1)}(t)) \]
where \( U_N(t) \) and \( A_N^{(1)}(t) \) is defined in (2.4) and (3.2), respectively, and
\[ \hat{U}_N(t) = N^{-1/2}(U_N(t) - \hat{A}_N^{(1)}(t)) \]
with
\[ \hat{A}_N^{(1)}(t) = \sum_{i=1}^{N} \hat{\alpha}_{i,t,1}, \quad \hat{\sigma}_i^2 = \frac{1}{N} \text{tr}(C_{i,t}(Z_{i,t}^{-1} - Z_{i,T}^{-1})) \]
and for \( \hat{\sigma}_i^2 \) we recommend the estimator defined in (3.10). In our study we use the test statistics
\[ \bar{\pi}_N = \max_t |\bar{U}_N(t)|, \quad \text{and} \quad \hat{\pi}_N = \max_t |\hat{U}_N(t)|. \]

Large values of either test statistics indicate that the null hypothesis is violated. The respective critical values are constructed via wild bootstrap. Notice that \( \bar{\pi}_N \) depends on \( \sigma_i^2 \)'s when these are replaced by their estimators \( \hat{\sigma}_i^2 \)'s. Since \( \sigma_i^2 \)'s are usually unknown the test statistic \( \hat{\pi}_N \) is more practical. In application we use \( \hat{\pi}_N \), but in the simulations we also present selected results for \( \bar{\pi}_N \) in order to see influence of unknown \( \sigma_i^2 \)'s.

Bellow we provide the algorithm for the test based on \( \hat{\pi}_N \) and level \( \alpha \)

**Algorithm**

(1) Compute \( \hat{A}_N^{(1)}(t), \hat{U}_N(t) \) and \( \hat{\pi}_N \) as described above and \( \hat{\sigma}_i^2 \) using formula (3.10).
(2) Generate bootstrap version \( u_N^* \):
   (a) Calculate \( \phi_{i,t} \) using
   \[ \phi_{i,t} = (\hat{\beta}_{i,t} - \hat{\beta}_{i,T})^T C_{i,t}(\hat{\beta}_{i,t} - \hat{\beta}_{i,T}) - \frac{1}{N} \sum_{j=1}^{N} (\hat{\beta}_{j,t} - \hat{\beta}_{j,T})^T C_{j,t}(\hat{\beta}_{j,t} - \hat{\beta}_{j,T}). \]
demonstrates how well the
to the corresponding significance level of the tests. Table
Our results show that, even for rather small
A. Empirical versus theoretical significance level
In simulations we first consider the case when non zero changes occur in all panels at the
1 000 and the number of bootstrap steps also equals 1 000. In our simulation setup we
assumptions on the errors terms. Overall, we keep the number of simulations equal to
Simulations.
The errors
\( \epsilon \) normally distributed with zero mean and variance
\( \sigma^2 \), that are generated from uniform distribution \( U(0.5, 1.5) \).
The “GARCH(1,1) process”: \( \epsilon_{i,t} = \nu_{i,t} \varepsilon_{i,t} \), where \( \nu_{i,t}^2 = 0.25 + 0.25 \varepsilon_{i,t-1}^2 + 0.5 \nu_{i,t-1}^2 \)
and \( \varepsilon_{i,t} \) are independent and follow the standard normal distribution \( N(0, 1) \).
In the sequel we report on two model specifications:
S1: Linear model with \( d = 2 \), \( \beta = (1, 2)^\top \) and \( C_{i,t} = Z_{i,t} Z_{i,t} \).
S2: Linear model with \( d = 5 \), \( \beta = (1, 1, 2, 3, 4)^\top \) and \( C_{i,t} = Z_{i,t} Z_{i,t}^{-1} Z_{i,t} \).
We use extensive simulations to explore finite sample properties of the underlying test
procedure. In particular, we analyze the significance level and the empirical power of the
test for different pairs of \( (N, T) \), different assumptions on \( t_0 \) (the change point) and various
assumptions on the errors terms. Overall, we keep the number of simulations equal to
1 000 and the number of bootstrap steps also equals 1 000. In our simulation setup we
also include cases when both \( N \) and \( T \) are small, to explore small sample properties of the
test statistics \( \overline{\alpha}_N \) and \( \widehat{\alpha}_N \) and the behavior of the proposed wild bootstrap procedure.
In simulations we first consider the case when non zero changes occur in all panels at the
same time \( t_0 \). Later we analyze the sensitivity of the detection of change in the case when
only a fraction of panels \( (\vartheta = 0.25) \) experience change. Selected results are presented
below.
A. Empirical versus theoretical significance level
Our results show that, even for rather small \( N \) and \( T \) the nominal rejection rate was close
to the corresponding significance level of the tests. Table 4.1 demonstrates how well the
nominal rejection of the null hypothesis (no change) in the case of model S2 corresponds to the chosen significance level, with four independent explanatory variables and intercept. A similar result is reported in Table 4.2 for model S1 for small $N$ and $T$. Other model assumptions (different number of regressors, different data generating process, different distributions) lead to similar results; additional results are available upon request.

B. Empirical power of the test statistic $\hat{u}_N$

In our simulation setup we set the time of change $t_0$ equal to $T/2$ and $T/4$ under $H_A$. Table 4.3 shows the empirical power of the tests based on $\bar{u}_N$ and $\hat{u}_N$ at a 5% significance level in case of model S2, for several combinations of $N$ and $T$. The empirical power is an increasing function of $N$ and $T$. It is high even for small and moderate $N$ and $T$, which can be explained by changes in all panels at the same time. We note that the estimation of the $\sigma^2_{\varepsilon}$’s reduces power but very mildly. By increasing $N$ for each $T$ we see the increasing empirical power of the test.

Similar results of the simpler model S1 with a sensitivity to different data generating processes are depicted in Table 4.4.
### Table 4.3. Power of the test based on \( \hat{\gamma}_N \) when the change occurs at \( t_0 = T/2 \) or \( T/4 \) in all regressors of model S2 (\( \delta = (0, 1, 0.3, 0.2, 0.1)^\top \)); the significance level 5%.

### C. Sensitivity analysis to fraction of panels experiencing a change

We also investigate a situation when only a fraction of the panels experience a change. The fraction of the panels with change is denoted by \( \vartheta \). Given the space limitations we present this sensitivity analysis only for the model S1 and for the case of \( \hat{\gamma}_N \) (\( \sigma_i^2 \) estimated by \( \hat{\sigma}_i^2 \)). The other setups lead to similar results. Bellow we present the results for model S1 when all changes occurred at time \( t_0 = T/2 \). We applied \( \hat{\gamma}_N \) to detect instability at a 5% significance level and the size of changes was \( \delta = (0.25, 0) \) (change in intercept) and \( \delta = (0, 0.25) \) (change in the slope). The results are presented in Table 4.5 when \( \vartheta = 0.25 \). For other \( \vartheta \) and \( \delta \) not presented here we observed the following pattern. The power of the test decreases with \( \vartheta \) (fraction of panels with changes) and increases with \( \delta \) (size of the change). The level of detection is very good, even if only a quarter of the panels contains changes in the regression parameters; one can see that the power of the test increases with \( T \) and with \( N \). Additional results are available upon request.
5. Empirical Illustration

In this section we present an application of our theoretical results to the capital asset pricing model (CAPM). We apply our approach to the CAPM, using the conventional factor model, which includes the Fama-French three-factor model augmented with the Carhart (1997) momentum factor.

Specifically, we test for breaks in coefficients for the US mutual fund return data around the sub-prime crisis. Our time span covers the period from January 2006 to February 2010, which is consistent with other sub-prime crisis studies (e.g. Dick-Nielsen et al., 2012). The sub-prime crisis is generally defined as the period between the fourth quarter of 2007 and the end of 2008 (Santos, 2011).

The Fama-French (1993) three factor model augmented with the Carhart (1997) momentum factor is defined as

\[ R_{i,t} - R^f_t = \alpha_{i,t} + (R^M_t - R^f_t)\beta_{i,t}^M + R^HML_t\beta_{i,t}^{HML} + R^SMB_t\beta_{i,t}^{SMB} + R^MOM_t\beta_{i,t}^{MOM} + e_{i,t}, \]

where \(1 \leq t \leq T, 1 \leq i \leq N\), where \(R_{i,t} - R^f_t\) denotes the excess return on the mutual fund; \(R^M_t - R^f_t\) is the market risk premium; \(R^HML_t\) is the value factor, calculated as the return difference between portfolios with the highest decile of stocks and the lowest decile of stocks in terms of the ratio of book equity-to-market equity (HML); \(R^SMB_t\) is the value factor, calculated as the return difference between portfolios with the smallest decile of stocks and the largest decile of stocks in terms of size (SMB); \(R^MOM_t\) is the momentum factor calculated as the return difference between portfolios with the highest decile of stocks and lowest decile of stocks in terms of recent return (i.e., momentum, or MOM); and \(e_{i,t}\) the random errors.

In our investigation we use \(\hat{u}_N\) as our test statistics and we display the graphs of \(|\hat{U}_N(t)|\). The unknown \(\sigma_i^2\) is estimated by \(\hat{\sigma}_i^2\) of (3.10). The critical values were obtained by the wild bootstrap of Section 4.1.
5.1. **Data Information.** The four factors can be downloaded from Ken French’s data library\(^1\). The raw dataset on mutual funds contains monthly return data of 6,190 US mutual funds from January 1984 to November 2014\(^2\). However, there are many missing values in the mutual fund dataset because different mutual funds have different start dates and some of them have already been terminated. For the purpose of our illustration we select the mutual funds that have no missing returns for the period of the subprime crisis (January 2006 to February 2010).

Using the Yahoo finance classification, we consider nine categories of the US mutual funds. These are *Large Blend, Large Growth, Large Value, Middle Blend, Middle Growth, Middle Value, Small Blend, Small Growth* and *Small Value*. These categories are combinations of the mutual fund size and their investment strategies as illustrated in Table 5.1.

\[
\begin{array}{ccc}
\text{Large} & \text{Medium} & \text{Small} \\
\text{Blend} & \text{Growth} & \text{Value}
\end{array}
\]

Table 5.1. Categories of mutual funds.

5.2. **Results for the sub-prime crisis.** Table 5.2 shows the test results for the sub-prime crisis. It covers the period from January 2006 to February 2010, which is equal to 50 periods. \(\hat{u}_N\) is the test statistic, \(CV\) stands for critical values which are reported for 10\%, 5\%, and 1\% significance levels obtained by the wild bootstrap. The *break point* column shows the month (time period) in which a break point was detected and \(N\) shows the number of observations per fund category. Between the brackets in the breakpoint column the estimated time of the change is reported.

For all but one fund categories the test statistic \(\hat{u}_N\) is above the 5\% critical values during the sub-prime crisis period (middle of 2008 to early 2009). Interestingly, the test cannot detect change for the category of Small Value mutual funds at the 5\% significance level. However the Small Value mutual fund category is significant at the 10\% significance level.

The coefficients for the four factors changed first for the Large Blend mutual fund category with estimated break point in August 2008, and the Small Growth mutual fund category has estimated change point just a month later in September 2008. The coefficients for Large Growth, Middle Blend, Middle Growth, and Small Blend changed last, in March 2009.

It is interesting to note that only the Large Blend indicated a change in the environment out of all large-type mutual funds. Recall that the Large Blend is defined as a balanced mix of growth and value stocks. We hypothesize that the Large Blend more closely resembles the market and that is why it indicated a shift in the underlying structure.

---

\(^1\)The factors data is available at [http://mba.tuck.dartmouth.edu/pages/faculty/ken.french/data_library.html](http://mba.tuck.dartmouth.edu/pages/faculty/ken.french/data_library.html)

\(^2\)The monthly return history of US mutual funds is available for the period January 1984 to November 2014 at the web site [http://finance.yahoo.com](http://finance.yahoo.com)
Figure 5.1 plots the estimated break points for the coefficients for the Mutual Fund categories with the levels of the S&P 500. The model employed is the Fama and French three factor model (1993) augmented with the Carhart (1997) momentum factor.

The Large Blend category indicated a structural change when the S&P 500 was well above the 1200 value. This could have been used as a potential trading signal. The lowest point of the S&P 500 was February 2009, below the 800 mark. Here the change point was detected for the Large Growth, Middle Blend, Middle Growth, and Small Blend. Again, as for the earlier estimated break point for Large Blend, this time could also be used as a trading signal, obviously indicating an upturn of the market.

Figures 5.2–5.10 graphically depict the processes $|\hat{U}_N(t)|$, estimated break point $\hat{t}_N$, and the estimated simulated critical values at the 10%, 5%, and 1% significance levels for all categories of mutual funds.

</table>
Figure 5.2 shows $|\hat{U}_N(t)|$ and simulated critical values for the category of Large Blend mutual funds. $|\hat{U}_N(t)|$ stays below the critical level up until late 2007 and then in 2008 it starts slowly breaking off. The estimated break point (corresponding to the highest value of $|\hat{U}_N(t)|$) is in August of 2008, but it is clear that in the preceding months an increase is visible. After the break in the coefficients, $|\hat{U}_N(t)|$ slowly decreased to regular levels in late 2009 and early 2010. Another peak in the first quarter of 2009, could suggest an influence of the European sovereign debt crisis, i.e., potentially two break points.

Figure 5.3 shows $|\hat{U}_N(t)|$ and simulated critical values for the category of Large Growth mutual funds. The estimated break point is in March of 2009, which is at the deepest point of the sub-prime crisis. However, the graph tells a slightly different story. $|\hat{U}_N(t)|$ is at zero in 2006 and 2007, and slowly increases in 2008. The process $|\hat{U}_N(t)|$ is well above the simulated critical values in late 2008 and all 2009, but the estimator of the time of a change is quite late due the magnitude of the March 2009 value. Immediately after the detection, $|\hat{U}_N(t)|$ quickly decreases below critical levels.
Figure 5.4. Graphs of $|\hat{U}_N(t)|$ and simulated critical values for Large Value mutual funds.

Figure 5.4 shows $|\hat{U}_N(t)|$ and simulated critical values for the category of Large Value mutual funds. The estimated break point is in February 2009. Obviously large mutual funds could be strongly influenced by the European sovereign debt crisis that started in early 2009. Again, a similar story emerges to the Large Value mutual fund. Values of $|\hat{U}_N(t)|$ are around zero and well below the simulated critical values in 2006, 2007, and early 2008. For most of 2008 the process $|\hat{U}_N(t)|$ is above the simulated critical values but the break point is again indicated late. After the estimated break in February $|\hat{U}_N(t)|$ drops below critical value levels.

Figure 5.5. Graphs of $|\hat{U}_N(t)|$ and simulated critical values for Middle Blend mutual funds.

Figure 5.6. Graphs of $|\hat{U}_N(t)|$ and simulated critical values for Middle Growth mutual funds.
Figures 5.5–5.7 show $\left| \hat{U}_N(t) \right|$ and simulated critical values for the category of Middle Blend, Middle Growth, and Middle Value mutual funds. The Middle Blend and Middle Growth mutual fund categories have an estimated break point in March 2009. For both mutual fund categories, $\left| \hat{U}_N(t) \right|$ remains fairly low up until early 2008. Even though the test statistic was above the simulated critical values in late 2008 and early 2009 the break point is indicated fairly late, in March 2009 for both funds. $\left| \hat{U}_N(t) \right|$ decreases to below simulated critical values shortly after the break detection. Middle Blend and Middle Growth mutual funds show a very similar pattern, suggesting two breakpoints. The first relates to the US crisis and the second to the European sovereign debt crisis. The European crisis is detected as the main break point for Middle Blend and Middle Growth mutual funds. Similar characteristics of $\left| \hat{U}_N(t) \right|$ are observed. The values remain very low and well below the simulated critical values up until late 2008. After the estimated break the values of $\left| \hat{U}_N(t) \right|$ remain quite high for a few months before dropping in late 2009.
Figures 5.8 – 5.10 show $|\tilde{U}_N(t)|$ and simulated critical values for the category of Small Blend, Small Growth, and Small Value mutual funds. The estimated break points for the Small Blend and Small Growth mutual funds are detected in March 2009 and September 2008, respectively. As is clearly visible, both graphs suggest possibility of two break points, as before. One is linked to the US mortgage crisis and the other to the European sovereign debt crisis. The test statistics for the maximum at these peaks are very similar. The simulated critical values were low until late 2008 and well below the significance levels.

The Small Value mutual fund category does not indicate a change point because the test statistic never exceeded the 5% critical value. However, a change is detected at the 10% level.

Overall, the result shows the sensitivity of large and medium mutual funds to the 2008 economic crisis, as well as the subsequent European sovereign debt crisis. For a detailed financial analysis of the associated change point it would be useful to classify the mutual funds according to their international portfolio holdings. The portfolio structure and its diversification could likely be attributed to a possible change. We leave these points for further research.

6. Conclusion and suggestions for further research

The detection of (structural) breaks has been at the center of both theoretical and applied economic and financial research for many years. Part of the existing research concentrates on the detection of breaks in panels when both $N$, the number of panels
and \( T \), the time dimension are large. In contrast, in this paper we concentrate on a qualitatively different situation. We elaborate a general approach for testing for the break(s) when \( N \) is large and \( T \) is fixed and rather small. This situation is typically related to large (firm-level) data containing financial information about an immense number of firms/stocks across a limited period of time. More precisely, we study the asymptotic properties of suggested test procedures when \( N \rightarrow \infty \) while keeping \( T \) fixed. Our approach also allows the estimation of the time of the change(s).

The goal of this paper is to present a background for constructing a set of quite general test statistics which are suitable in the given context, and to prove theorems about their asymptotic behavior. We also aim to show that several special choices of the weighting matrices used in our test statistics resulted in a generalization of some well-known test statistics.

In the rich simulation section we study the finite sample properties of two processes. The maximum norm of these processes can be used as test statistics and critical values obtained by a wild bootstrap. We present a selected set of tables to document the accuracy of the significance levels and the power of the test under several simulation schemes and alternatives, including cases when only a fraction of the panels experienced a break.

For a practical application we apply the testing procedure in the framework of the four factors CAPM model. In particular, we estimate breaks in monthly returns of US mutual funds during the period January 2006 to February 2010 which covers the subprime crises.

The theoretical considerations concerning multiple breaks are beyond the scope of this paper and we plan to address them in future research.

7. Proofs

We assume that $H_0$ holds. Using (1.1) we get

$$\hat{\beta}_{i,t} = \beta_i + Z_{i,t}^{-1}(S_{i,t} + R_{i,t}),$$
where $S_{i,t}, R_{i,t} \in R^d$, $S_{i,t}$ is defined in (3.5) and $R_{i,t} = \sum_{s=1}^{t} x_{i,s} \gamma_i^\top A_s$, $1 \leq i \leq N, 1 \leq t \leq T$. It also holds that

\[
(\hat{\beta}_{i,t} - \hat{\beta}_{i,T})^\top C_{i,t} (\hat{\beta}_{i,t} - \hat{\beta}_{i,T}) = S_{i,t}^\top C_{i,t} S_{i,t} + S_{i,T}^\top C_{i,t} S_{i,T} - 2 S_{i,t}^\top C_{i,t} \bar{S}_{i,t} - 2 S_{i,t}^\top C_{i,t} \bar{R}_{i,t} \\
+ 2 S_{i,T}^\top C_{i,t} \bar{R}_{i,T} - 2 S_{i,T}^\top C_{i,t} \bar{S}_{i,T} - 2 R_{i,t}^\top C_{i,t} \bar{R}_{i,t} + R_{i,t}^\top C_{i,t} \bar{R}_{i,t},
\]

where

\[
C_{i,t,1} = Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1}, \quad C_{i,t,2} = Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1}, \quad \text{and} \quad C_{i,t,3} = Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1}.
\]

**Lemma 7.1.** If $H_0$ and Assumptions 2.1–2.3 and 2.5–2.7 hold, then we have that

\[
E S_{i,t}^\top C_{i,t,1} S_{i,t} = \sigma_i^2 \sum_{s=1}^{t} x_{i,s}^\top C_{i,t,1} x_{i,s} \sigma_i^2 \mathrm{tr} \left( C_{i,t,1} Z_{i,t} \right),
\]

\[
E S_{i,T}^\top C_{i,t,2} S_{i,T} = \sigma_i^2 \sum_{s=1}^{T} x_{i,s}^\top C_{i,t,2} x_{i,s} \sigma_i^2 \mathrm{tr} \left( C_{i,t,2} Z_{i,T} \right)
\]

and

\[
E S_{i,T}^\top C_{i,t,3} S_{i,T} = \sigma_i^2 \sum_{s=1}^{T} x_{i,s}^\top C_{i,t,3} x_{i,s} \sigma_i^2 \mathrm{tr} \left( C_{i,t,3} Z_{i,T} \right).
\]

**Proof.** With the notation $C_{i,t,1} = \{c_{i,t,1}(\ell, \ell'), 1 \leq \ell, \ell' \leq d\}$ and $S_{i,t} = (S_{i,t}(1), \ldots, S_{i,t}^d)^\top$ we have

\[
S_{i,t}^\top C_{i,t,1} S_{i,t} = \sum_{s=1}^{t} x_{i,s}^\top \varepsilon_{i,s} Z_{i,t}^{-1} C_{i,t} Z_{i,t}^{-1} \sum_{v=1}^{t} x_{i,v} \varepsilon_{i,v}
\]

\[
= \sum_{s=1}^{d} \sum_{s=1}^{d} S_{i,t}(\ell) c_{i,t,1}(\ell, \ell') S_{i,t}(\ell')
\]

\[
= \sum_{s=1}^{d} \sum_{s=1}^{d} \sum_{s=1}^{d} \sum_{s'=1}^{d} x_{i,s}(\ell) x_{i,s'}(\ell') \varepsilon_{i,s} \varepsilon_{i,s'} c_{i,t,1}(\ell, \ell'),
\]

which implies the first statement of the lemma since $E \varepsilon_{i,s} \varepsilon_{i,s'} = \sigma_i^2$ if $s = s'$, and zero otherwise. The same argument can be used to prove the rest of Lemma 7.1.

\[\square\]

Let

\[
H_{i,t} = S_{i,t}^\top C_{i,t,1} S_{i,t} + S_{i,T}^\top C_{i,t,2} S_{i,T} - 2 S_{i,t}^\top C_{i,t,3} S_{i,T}.
\]

**Lemma 7.2.** If $H_0$ and Assumptions 2.1–2.7 and 3.1 hold, then we have

\[
\left\{ N^{-1/2} \sum_{i=1}^{N} (H_{i,t} - \sigma_i^2), \quad d \leq t \leq T \right\} \overset{D}{\rightarrow} \left\{ \xi^{(1)}_i, L_0 \leq t \leq T - \bar{t}_0 \right\},
\]

where $\xi^{(1)}_i, L_0 \leq t \leq T - \bar{t}_0$, is jointly normal with zero mean and covariance $\Gamma^{(1)}(t, t')$ and $L_0, \bar{t}_0$ are defined in Assumption 3.1.
Proof. It follows from Assumptions 2.2, 2.6 and 2.7 that the random vectors \( H_{i,t}, L_0 \leq t \leq T - \bar{t}_0 \) are independent and by Lemma 7.1 \( E H_{i,t} = a_{i,t,1}^2 \). Also, that \( E |H_{i,t} - a_{i,t,1}^2|^\kappa/2 \leq c E |\epsilon_{i,0}|^\kappa \) and therefore we have

\[
\sum_{i=1}^{N} E |H_{i,t} - a_{i,t,1}^2|^\kappa/2 = O(N). \tag{7.4}
\]

It is easy to see that

\[
\text{cov} \left( H_{i,t}, H_{i,t'} \right) = E \left[ (Z_{i,t}^{-1}S_{i,t} - Z_{i,t}^{-1}S_{i,T})^\top C_{i,t}(Z_{i,t}^{-1}S_{i,t} - Z_{i,t}^{-1}S_{i,T}) \right. \\
\left. \times (Z_{i,t'}^{-1}S_{i,t'} - Z_{i,t'}^{-1}S_{i,T})^\top C_{i,t'}(Z_{i,t'}^{-1}S_{i,t'} - Z_{i,t'}^{-1}S_{i,T}) \right] - a_{i,t,1}^2 a_{i,t',1}^2.
\]

We can assume that \( \{\Gamma^{(1)}(t, t'), \bar{t}_0 \leq t, t' \leq T - \bar{t}_0 \} \) is a non–singular matrix. If \( \Gamma^{(1)}(t, t') \) is singular, one needs to prove the central limit theorem for a subvector of \( (H_{i,\bar{t}_0}, \ldots, H_{i,T-\bar{t}_0})^\top \) such that the related submatrix of \( \Gamma^{(1)}(t, t') \) is regular and has the same rank as \( \Gamma^{(1)}(t, t') \). Hence for any constants \( (c_{\bar{t}_0}, c_{\bar{t}_0+1}, \ldots, c_{T-\bar{t}_0}) \neq 0 \) we have

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \text{var} \left( \sum_{v=\bar{t}_0}^{T-\bar{t}_0} c_v H_{i,v} \right) > 0.
\]

Equation (7.4) implies that

\[
\sum_{i=1}^{N} E \left| \sum_{v=\bar{t}_0}^{T-\bar{t}_0} c_v (H_{i,v} - a_{i,v,1}^2) \right|^\kappa/2 = O(N).
\]

Hence Lemma 7.2 follows from Lyapunov’s theorem (cf. Petrov (1995, p. 122)).

\[\Box\]

Lemma 7.3. If \( H_0 \) and Assumptions 2.1–2.7 hold, then we have for all \( \bar{t}_0 \leq t \leq T - \bar{t}_0 \) that

\[
\sum_{i=1}^{N} S_{i,t}^\top C_{i,t,1} R_{i,t} = o_P(N^{1/2}), \quad \sum_{i=1}^{N} S_{i,t}^\top C_{i,t,3} R_{i,t} = o_P(N^{1/2})
\]

and

\[
\sum_{i=1}^{N} S_{i,t}^\top C_{i,t,2} R_{i,t} = o_P(N^{1/2}), \quad \sum_{i=1}^{N} R_{i,t}^\top C_{i,t,3} S_{i,t} = o_P(N^{1/2}),
\]

where \( \bar{t}_0 \) and \( \bar{t}_0 \) are defined in Assumption 3.1.

Proof. Using Assumptions 2.1–2.3 we conclude that \( ES_{i,t}^\top C_{i,t,1} R_{i,t} = 0 \) and

\[
\text{var} \left( \sum_{i=1}^{N} S_{i,t}^\top C_{i,t,1} R_{i,t} \right) = \sum_{i=1}^{N} E (S_{i,t}^\top C_{i,t,1} R_{i,t})^2. \tag{7.5}
\]

Next we note that \( (S_{i,t}^\top C_{i,t,1} R_{i,t})^2 \leq \|S_{i,t}\|^2\|C_{i,t,1}\|\|R_{i,t}\|^2 \leq c\|S_{i,t}\|^2\|R_{i,t}\|^2 \) with some constant on account of Assumption 2.6–2.7. Using again Assumption 2.6 we get that \( E \|S_{i,t}\|^2 \leq c\sigma^2 \) and \( E \|R_{i,t}\|^2 \leq c\|\gamma_i\|^2 \) with some constant \( c \). On account of Assumption 2.2(ii) we conclude
\[
\text{var} \left( \sum_{i=1}^{N} S_{i,t}^\top C_{i,t,1} R_{i,t} \right) = O(1) \sum_{i=1}^{N} \sigma_i^2 \| \gamma_i \|^2 = O(1) \sum_{i=1}^{N} \| \gamma_i \|^2,
\]
and therefore Chebyshev’s inequality and Assumption 2.4 imply the first statement in Lemma 7.3. The same argument can be used to prove the other upper bounds.

**Lemma 7.4.** If $H_0$ and Assumptions 2.1 and 2.3–2.7 hold, then we have for all $t_0 \leq t \leq T$ that
\[
\sum_{i=1}^{N} R_{i,t}^\top C_{i,t,1} R_{i,t} = o_P(N^{1/2}), \quad \sum_{i=1}^{N} R_{i,T}^\top C_{i,t,2} R_{i,T} = o_P(N^{1/2})
\]
and
\[
\sum_{i=1}^{N} R_{i,t}^\top C_{i,t,3} R_{i,T} = o_P(N^{1/2}),
\]
where $t_0$ and $\bar{t}_0$ are defined in Assumption 3.1.

**Proof.** Using Assumptions 2.6 and 2.7 we get that
\[
\left| \sum_{i=1}^{N} R_{i,t}^\top C_{i,t,1} R_{i,t} \right| \leq \sum_{i=1}^{N} \sum_{s=1}^{t} \sum_{s'=1}^{t} |x_{i,s}^\top C_{i,t,1} x_{i,s'} \gamma_i^\top \Lambda_s \gamma_i \Lambda_{s'} |
\]
\[
= O_P(1) \sum_{i=1}^{N} \| \gamma_i \|^2,
\]
and therefore the first part follows from Assumption 2.4. The remaining three cases can be proven in a similar way and therefore the details are omitted.

**Proof of Theorem 3.1.** The result follows immediately from Lemmas 7.1–7.4.

To prove Theorem 3.2 we note that
\[
\hat{e}_{i,t} = w_{i,t} + r_{i,t}, \quad \text{where} \quad w_{i,t} = \varepsilon_{i,t} - x_{i,t}^\top Z_{i,T}^{-1} S_{i,T} \quad \text{and} \quad r_{i,t} = \gamma_i^\top \Lambda_i - x_{i,t}^\top Z_{i,T}^{-1} J_{i,T}
\]
with
\[
J_{i,t} = \sum_{v=1}^{t} x_{i,v} \gamma_i^\top \Lambda_v.
\]
Hence
\[
\hat{e}_{i,t}^2 = w_{i,t}^2 + 2w_{i,t} r_{i,t} + r_{i,t}^2.
\]

**Lemma 7.5.** If $H_0$ and Assumptions 2.1–2.6 and 3.2 hold, then we have
\[
\left\{ N^{-1/2} \sum_{i=1}^{N} \left( \sum_{s=1}^{t} w_{i,s}^2 - a_{i,t,2}^2 \right), 1 \leq t \leq T \right\} \xrightarrow{P} \left\{ \xi_t^{(2)}, 1 \leq t \leq T \right\},
\]
where $\xi_t^{(2)}, 1 \leq t \leq T$ is jointly normal with zero mean and covariance $\Gamma^{(2)}(t,t').$
Proof. It is easy to see that \( E w_{i,s} = \sigma_{i,s}^2 (1 - x_i^\top Z_i^{-1} x_i) \). It follows from Assumptions 2.2, 2.5 and 2.6 that \( E |w_{i,s}^2 - E w_{i,s}^2|^{\kappa/2} \leq c E \varepsilon_{i,s}^{\kappa} \) with some \( c \) and therefore

\[
(7.6) \quad \sum_{i=1}^N E \left| \sum_{t=1}^T c_t \left( \sum_{s=1}^t w_{i,s}^2 - a_{i,t,2}^2 \right) \right|^{\kappa/2} = O(N).
\]

As in the proof of Lemma 7.2, we can assume without loss of generality that \( \Gamma^{(2)}(t, r') \) is non–singular. Hence for all \( (c_1, c_2, \ldots, c_T)^\top \neq 0 \) we have that

\[
\lim_{N \to \infty} \frac{1}{N} \sum_{i=1}^N \text{var} \left( \sum_{t=1}^T c_t \left( \sum_{s=1}^t w_{i,s}^2 - a_{i,t,2}^2 \right) \right) > 0.
\]

We get from (7.6) that

\[
\sum_{i=1}^N E \left| \sum_{t=1}^T c_t \left( \sum_{s=1}^t w_{i,s}^2 - a_{i,t,2}^2 \right) \right|^{\kappa/2} = O(N).
\]

Now the lemma follows from Lyapunov’s theorem (cf. Petrov (1995, p. 122)) and the Cramér–Wold lemma (cf. Billingsley (1968)). \( \square \)

Lemma 7.6. If \( H_0 \) and Assumptions 2.1–2.6 and 3.2 hold, then we have for all \( 1 \leq t \leq T \) that

\[
\sum_{i=1}^N r_{i,t}^2 = o_P(N^{1/2})
\]

and

\[
\sum_{i=1}^N r_{i,t} w_{i,t} = o_P(N^{1/2}).
\]

Proof. We note that

\[
r_{i,t}^2 \leq 2 \| \gamma_i \|^2 \| \Lambda_t \|^2 + 2 \left( x_i^\top Z_i^{-1} J_{i,t} \right)^2
\]

and by Assumption 2.4

\[
\sum_{i=1}^N \| \gamma_i \|^2 \| \Lambda_t \|^2 = o_P(N^{1/2}).
\]

Also, by Assumptions 2.5 and 2.6 we have

\[
\left( x_i^\top Z_i^{-1} J_{i,T} \right)^2 \leq c \| J_{i,T} \|^2 \leq c
\]

and therefore

\[
\sum_{i=1}^N \left( x_i^\top Z_i^{-1} J_{i,T} \right)^2 = O(1) \max_{1 \leq s \leq T} \| \Lambda_s \|^2 \sum_{i=1}^N \| \gamma_i \|^2 = o_P(N^{1/2}),
\]

completing the proof of the first part of Lemma 7.6.

We write that

\[
w_{i,t,r_{i,t}} = \varepsilon_{i,t} \gamma_{i,t}^\top \Lambda_t - \varepsilon_{i,t} x_i^\top Z_i^{-1} J_{i,T} - x_i^\top Z_i^{-1} S_i J_{i,T} \gamma_t^\top \Lambda_t + x_i^\top Z_i^{-1} S_i J_{i,T} x_i^\top Z_i^{-1} J_{i,T} \gamma_t.
\]

Using Assumptions 2.1–2.3 we get that \( E \varepsilon_{i,t} \gamma_{i,t}^\top \Lambda_t = 0 \) and

\[
\text{var} \left( \sum_{i=1}^N \varepsilon_{i,t} \gamma_{i,t}^\top \Lambda_t \right) = O(1) \sum_{i=1}^N \| \gamma_i \|^2 = O(N^{1/2})
\]
on account of Assumption 2.4. Similarly, \( E \varepsilon_{i,t}x_{i,t}^\top Z_{i,t}^{-1}J_{i,T} = 0 \) and
\[
\text{var} \left( \sum_{i=1}^{N} \varepsilon_{i,t}x_{i,t}^\top Z_{i,i}^{-1}J_{i,i} \right) = O(N^{1/2}).
\]
Repeating the arguments above, one can verify that
\[
\left| \sum_{i=1}^{N} x_{i,t}Z_{i,T}^{-1}S_{i,T} \gamma_{i}^\top \Lambda_{i} \right| = O_{P}(N^{1/4})
\]
and
\[
\left| \sum_{i=1}^{N} x_{i,t}Z_{i,T}^{-1}S_{i,T} x_{i,t}Z_{i,T}^{-1}J_{i,T} \right| = O_{P}(N^{1/4}),
\]
completing the proof of the second part of Lemma 7.6.

\[\square\]

**Proof of Theorem 3.2.** It is an immediate consequence of Lemmas 7.5 and 7.6. \[\square\]

**Proof of Theorem 3.3.** It follows from the proof of Lemma 7.2 that
\[
\sum_{i=1}^{N} H_{i,t} - A_{N}^{(1)}(t) = O_{P}(N^{1/2}),
\]
without assuming the existence of the limit in Assumption 3.1, since under the conditions of Theorem 3.3
\[
\limsup_{N \to \infty} \frac{1}{N} \sum_{i=1}^{N} \left\{ E \left( (Z_{i,T}^{-1}S_{i,T} - Z_{i,T}^{-1}S_{i,T})^\top bC_{i,t}(Z_{i,T}^{-1}S_{i,t} - Z_{i,T}^{-1}S_{i,t}) \right) \right. \\
\times (Z_{i,T}^{-1}S_{i,t'} - Z_{i,T}^{-1}S_{i,T})^\top C_{i,t'}(Z_{i,T}^{-1}S_{i,t'} - Z_{i,T}^{-1}S_{i,T}) \left\} - a_{i,t,1}a_{i,t',1}^2 \right| < \infty.
\]
Elementary arguments give
\[
\Pi_{i,t} = \sum_{s,v=1}^{t} A_{s}^\top \gamma_{i} x_{i,s}^\top (Z_{i,t}^{-1} - Z_{i,T}^{-1})C_{i,t}(Z_{i,t}^{-1} - Z_{i,T}^{-1}) \gamma_{i}^\top \Lambda_{v},
\]
where
\[
\Pi_{i,t} = R_{i,t}^\top C_{i,t,1}R_{i,t} + R_{i,T}^\top C_{i,t,2}R_{i,T} - 2R_{i,T}^\top C_{i,t,3}R_{i,T}
\]
\[
= \gamma_{i}^\top \left( \sum_{j=1}^{t} A_{j} x_{i,j}^\top Z_{i,t}^{-1} - \sum_{j=1}^{T} A_{j} x_{i,j}^\top Z_{i,T}^{-1} \right) C_{i,t} \left( Z_{i,t}^{-1} \sum_{v=1}^{t} x_{iv} \Lambda_{v}^T - Z_{i,T}^{-1} \sum_{v=1}^{T} x_{iv} \Lambda_{v}^T \right) \gamma_{i}
\]
\[
= \sum_{j=1}^{t} \sum_{v=1}^{t} A_{j}^\top \gamma_{i} x_{i,j}^\top (Z_{i,t}^{-1}I\{1 \leq j \leq t\} - Z_{i,T}^{-1})C_{i,t} \left( Z_{i,t}^{-1}I\{1 \leq v \leq t\} - Z_{i,T}^{-1} \right) x_{iv} \gamma_{i} \Lambda_{v}
\]
Hence the definition of the function \( Q \) yields
\[
\frac{1}{r_{N}} \sum_{i=1}^{N} \Pi_{i,t} \to \sum_{s,v=1}^{t} A_{s}^\top Q(s,v,t) \Lambda_{v} \quad \text{a.s.}
\]
We showed in the proof of Lemma 7.3 that
\[ \sum_{i=1}^{N} S_{i,t}^\tau C_{i,t} R_{i,t} = O_P(1) \sum_{i=1}^{N} \| \gamma_i \|^2, \quad \sum_{i=1}^{N} S_{i,T}^\tau C_{i,t} R_{i,t} = O_P(1) \sum_{i=1}^{N} \| \gamma_i \|^2 \]
and
\[ \sum_{i=1}^{N} S_{i,t}^\tau C_{i,t} R_{i,t} = O_P(1) \sum_{i=1}^{N} \| \gamma_i \|^2, \quad \sum_{i=1}^{N} R_{i,t} C_{i,t} S_{i,t} = O_P(1) \sum_{i=1}^{N} \| \gamma_i \|^2. \]
The proof of Theorem 3.3 is now complete. \( \square \)

**Proof of Theorem 3.4.** Elementary arguments give
\[ r_{i,t}^2 = \Lambda_t^\tau \gamma_i^\tau \Lambda_t - 2 \sum_{i=1}^{N} A_{i,t}^\tau \gamma_i^\tau Z_{i,t}^\tau x_i \gamma_i^\tau + \sum_{i=1}^{T} A_{i,t}^\tau \gamma_i^\tau x_i \gamma_i^\tau Z_{i,t}^\tau x_i, \gamma_i^\tau \Lambda_t. \]

Using Assumption 3.5 we obtain that
\[ \left\{ \frac{1}{N} \sum_{i=1}^{N} r_{i,t}^2, 1 \leq t \leq T \right\} \rightarrow \left\{ \xi_t^{(4)}, 1 \leq t \leq T \right\} \quad \text{a.s..} \]
It follows from the proof of Theorem 3.2 that
\[ \sum_{i=1}^{N} w_{i,t}^2 - A_{i,N}^{(2)}(t) = O_P(N^{1/2}). \]
Minor modification of the proof of Theorem 3.3 gives
\[ \sum_{i=1}^{N} w_{i,t} r_{i,t} = o_P(r_N), \]
and therefore (3.15) is proven. \( \square \)

**Proof of Theorem 4.1** Let \( \overline{\beta}_{i,t} \) and \( \overline{\beta}_{i,T} \) denote the OLS estimators when \( \gamma_i = 0, 1 \leq i \leq N \) and define
\[ \overline{\gamma}_{i,t} = (\overline{\beta}_{i,t} - \overline{\beta}_{i,T})^\tau C_{i,t}(\overline{\beta}_{i,t} - \overline{\beta}_{i,T}) - \frac{1}{N} \sum_{j=1}^{N} (\overline{\beta}_{j,t} - \overline{\beta}_{j,T})^\tau C_{j,t}(\overline{\beta}_{j,t} - \overline{\beta}_{j,T}). \]
Using Assumption 2.4 one can show that
\[ (7.7) \quad \left| U_N^*(t) - N^{-1/2} \sum_{i=1}^{N} \zeta_t \overline{\gamma}_{i,t} \right| = O_P(1), \quad T_0 \leq t \leq T_0. \]
Note that \( \{ \zeta_t \overline{\gamma}_{i,t}, T_0 \leq t \leq T_0 \} \) are independent vectors with zero mean. Let \( \lambda_{T_0}, \ldots, \lambda_{T-T_0} \) be arbitrary constant and define linear combinations
\[ z_i = \zeta_t \sum_{i=1}^{T-T_0} \lambda_{T-T_0} \overline{\gamma}_{i,t}. \]
It follows from Assumption 3.1 along the lines of the proof of Theorem 3.1 that
\[ E \left( \frac{1}{\sqrt{N}} \sum_{i=1}^{N} z_i \right)^2 \rightarrow \sum_{i=1}^{T-T_0} \sum_{s=T_0}^{T-T_0} \lambda_{T-T_0} \Gamma^{(1)}(t, s) \lambda_s. \]
Also, on account of Assumption 2.2 we have that $E|z_i|^{1+\kappa/2}$ is uniformly bounded. Hence by the Cramér-Wold device (cf. Billingsley, 1968)

$$\left\{ N^{-1/2} \sum_{i=1}^{N} \zeta_i \overline{\Phi}_{i,t}, t_0 \leq t \leq t_0 \right\} \overset{D}{\to} \left\{ \xi_1^{(t)}, t_0 \leq t \leq t_0 \right\}. $$

To prove the second part of the theorem we note that (7.7) holds under alternatives. It is easy to see that

$$E\left( N^{-1/2} \sum_{i=1}^{N} \zeta_i \overline{\Phi}_{i,t} \right)^2 = O(1).$$

The proof is complete. \qed
