28 **Abstract**

29 The electrochemical synthesis of hydrogen peroxide ( $H_2O_2$ ) represents a promising  
30 alternative to the anthraquinone process, as it combines on-site chemical and electrical  
31 production. The design of selective electrocatalysts is challenging and is commonly  
32 based on the alloying of elements to generate a synergistic effects and increase activity.  
33 In the present work, we report the electrochemical activity of Au-Pd nanoparticles  
34 immobilized directly onto an electrode as a model to study  $H_2O_2$  electrochemical  
35 synthesis from fundamentals to continuous production. The impact of composition on  
36 the oxygen reduction (ORR), on the selectivity, as well as the peroxide reduction and  
37 oxidation (PROR) are studied.

42

## 43 **1 Introduction**

44 Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) is an excellent green oxidant applied in several important  
45 processes, for instance pulp and paper bleaching, water-cleaning, disinfection and  
46 industrial synthesis of consumer goods [1, 2]. At present, H<sub>2</sub>O<sub>2</sub> is manufactured almost  
47 exclusively through the anthraquinone process in centralized reactors, where it is often  
48 concentrated up to 70 wt% to reduce costs [3]. However, as typical end-users require  
49 concentrations of 2-8 wt% [2], local production by means of a less energy demanding  
50 synthetic technology is desirable [4].

51 Electrochemical reactors represent an attractive alternative for the production of H<sub>2</sub>O<sub>2</sub>  
52 via O<sub>2</sub> reduction on-site. Intensive research has been carried out over recent years both  
53 in alkaline [5, 6] and acidic medium [7-9]. However, as H<sub>2</sub>O<sub>2</sub> degradation can be base  
54 catalysed, more promising is the synthesis in acidic medium [10]. In acid, H<sub>2</sub>O<sub>2</sub> is  
55 synthesized from O<sub>2</sub> and protons in a 2-electron ORR pathway ( $\text{O}_{2(\text{g})} + 2\text{H}^{+}_{(\text{aq})} + 2\text{e}^{-} \rightarrow$   
56  $\text{H}_2\text{O}_{2(\text{aq})}$ ) [11]; its standard potential is 0.69 V [12]. The well-developed technology of  
57 proton exchange membrane fuel cells (PEM-FC) could be directly utilized for eventual  
58 H<sub>2</sub>O<sub>2</sub> production and collection of electrical current on a larger scale.

59 Noble metals such as Pt and Pd are the most promising PEM-FC catalysts, due to their  
60 high stability at potentials of operational interest in acidic environments [12]. However,  
61 both tend to reduce O<sub>2</sub> to H<sub>2</sub>O in a 4-electron pathway with high faradaic efficiencies  
62 [11]. Recently, the addition of mercury to Pt or Pd led to the discovery of  
63 unprecedentedly active electrocatalyst for the H<sub>2</sub>O<sub>2</sub> synthesis, which was ascribed to the  
64 synergetic presence of two metals with different oxygen binding energies [8, 13].  
65 However, the toxicity of Hg might ultimately limit the application of these alloys. Au and  
66 Au-Pd catalysts were shown to have the lowest overpotential besides Hg-based catalysts  
67 [8]. Au and Pd are safe and, thanks to their high dissolution onset-potential, also  
68 promising candidates in acidic media [14]. In addition AuPd nanoparticles supported on  
69 carbon and oxide materials have been extensively studied as heterogeneous catalysts for  
70 direct H<sub>2</sub>O<sub>2</sub> synthesis from molecular H<sub>2</sub> and O<sub>2</sub> [15].

71 Pd binds oxygen intermediates strongly and has a low ORR overpotential close to Pt  
72 [16]. Au shows remarkable variation in the kinetics and the mechanism of the ORR  
73 varying between 2- and 4-electrons process, depending on support, crystallographic  
74 orientation, size and pH [17-19]. Such behavior is common to all electrodes that interact  
75 weakly with O<sub>2</sub> (i.e. Au, Ag, Hg) [17, 20]. The alloy of Au and Pd, has been shown to  
76 influence activity and selectivity for the ORR [7, 21, 22]. Jirkovsky *et al.* studied the  
77 influence of carbon supported Au-Pd catalysts (Pd < 50%) and showed that the addition  
78 of a small fraction (8%) of Pd leads to an increase in H<sub>2</sub>O<sub>2</sub> selectivity compared to pure  
79 Au [7]. This was attributed to the ensemble (or geometric) effect caused by the presence  
80 of finely dispersed Pd in Au, influencing the O<sub>2</sub> adsorption on the catalyst surface [23].  
81 Erikson *et al.* studied the ORR behavior of Au-Pd electrodeposited catalysts with higher  
82 Pd% (only Pd > 50%) however particle size distributions were variable between  
83 samples [22].

84 In this context, we studied the performance of colloidal AuPd nanoparticles immobilized  
85 directly onto an electrode over a wide range between pure Au and Pd (Au, Au<sub>9</sub>Pd, Au<sub>3</sub>Pd,  
86 AuPd, AuPd<sub>3</sub>, Pd) and with controlled particle size distributions around 3-4 nm  
87 (statistical size from TEM micrographs). In particular, we present their ORR activity,  
88 H<sub>2</sub>O<sub>2</sub> selectivity and the PROR in an acidic environment with the rotating ring-disc  
89 electrode (RRDE). Finally, potentiostatic production of H<sub>2</sub>O<sub>2</sub> (2 and 30 min) provides us  
90 additional information on the catalyst behavior in real systems.

## 91 **2 Materials and Methods**

### 92 ***2.1 Nanoparticle synthesis and characterization***

93 For the preparation of Au-Pd nanoparticles a colloidal synthesis method described  
94 elsewhere was followed [24]. An aqueous solution (800 ml, HPLC grade water)  
95 containing metal precursors in the desired ratio was prepared from stock solutions of  
96 PdCl<sub>2</sub> (6 mg<sub>Pd</sub> ml<sup>-1</sup>, Sigma Aldrich, Reagent Plus® 99%) and HAuCl<sub>4</sub> · 3H<sub>2</sub>O (12.5 mg<sub>Au</sub> ml<sup>-1</sup>  
97 Sigma Aldrich, Au assay ≥49.0%) with a total metal content of 20 mg metal in 800 ml.  
98 Separately aqueous solutions of NaBH<sub>4</sub> (Sigma Aldrich, 0.1 M) and Poly(vinyl alcohol)  
99 (PVA) (1 wt% aqueous solution, Sigma Aldrich, MW=10,000, 80% hydrolyzed) were also  
100 prepared. PVA addition to the metal solution (PVA/(Au + Pd) (w/w)=1.2) was followed  
101 by addition of a freshly prepared solution of NaBH<sub>4</sub> (0.1 M, NaBH<sub>4</sub>/(Au + Pd)  
102 (mol/mol)=5) to form a dark-brown sol which is generated in 30 min. The obtained  
103 solutions were finally concentrated with the help of a rotary evaporator to 0.1 mg ml<sup>-1</sup>.

104 For examination by scanning transmission electron microscopy (STEM), to determine  
105 the particle size distributions, a JEOL 2200FS TEM operating at 200 kV was used. The  
106 prepared solutions were dispersed onto a lacey carbon film supported by a gold TEM  
107 grid and then subjected to bright field contrast.

108 The Au:Pd molar ratios were measured by ICP-MS (NexION 300X, Perkin Elmer) by  
109 dissolving the AuPd samples in boiling aqua regia (4 ml solution, Merck Suprapur acids).

110 XPS measurements were performed applying a monochromatic Al K $\alpha$  X-ray source  
111 (1486.6 eV) operating at 15 kV and 25 W (Quantera II, Physical Electronics,  
112 Chanhassen). Analysis of the spectra was carried out using Casa XPS  
113 (<http://www.casaxps.com/>).

### 114 ***2.2 Electrochemical characterization***

115

116 All electrochemical results were obtained via thin-film technique either on a rotating  
117 disc electrode (RDE, Ar background and PROR) or rotating ring-disc electrode (RRDE)  
118 method. Experiments were carried out at room temperature ( $\approx 24^\circ\text{C}$ ) in a three electrode  
119 Teflon cell and potentials refers to the reversible hydrogen electrode (RHE), measured  
120 prior to experiments. Mirror polished poly-Pt, poly-Au, poly-Pd (5 mm, MaTeck) and Au-  
121 Pd catalysts (10  $\mu\text{g}_{\text{metal}} \text{cm}^{-2}$ ) on glassy carbon (GC) with an area of 0.196 cm<sup>2</sup> were  
122 alternated as working electrodes. Both the counter electrode, a graphite rod, and the  
123 reference electrode, a saturated Ag/AgCl electrode (Metrohm), were separated by a  
124 Nafion membrane (Tschurl modification). Potentiostat (Gamry Reference 600) and  
125 rotator (MSR Pine Rotator System) were controlled with a Gamry V6 Software. The  
126 supporting electrolyte was gas (Ar or O<sub>2</sub>) purged 0.1 M HClO<sub>4</sub>, prepared by dilution of

127 concentrated perchloric acid (Suprapur®, Merck) in ultrapure water (PureLab Plus  
 128 system, Elga, 18 MΩ-cm). For PROR, 10 mM H<sub>2</sub>O<sub>2</sub> (AnalaR NORMAPUR) were added to  
 129 the Ar purged electrolyte. More details about the single electrochemical method are  
 130 available in the SI.

131

## 132 3 Results and discussion

### 133 3.1 TEM and Surface Characterization

134

135 **Figure 1 (a) Representative bright field TEM micrograph and (b) statistic particle size distribution of Au**  
 136 **colloidal nanoparticles deposited on a lacey carbon TEM grid. The micrographs of the other prepared**  
 137 **catalysts are shown in the SI. (c) XPS spectra for the series of freshly prepared Au-Pd catalysts and (d)**  
 138 **corresponding initial cyclic voltammograms [0.1-1.6] V<sub>RHE</sub> in Ar purged 0.1M HClO<sub>4</sub>. Scan rate: 200 mV s<sup>-1</sup>.**

139

140 The Au-Pd nanoparticles (Au, Au<sub>9</sub>Pd, Au<sub>3</sub>Pd, AuPd, AuPd<sub>3</sub>, Pd) are prepared through a  
 141 sol-immobilization method yielding the presence of a face-centered cubic (fcc) structure,  
 142 as recently described [24]. The average particle size and size distribution are estimated  
 143 statistically from bright field STEM micrographs (Figure 1a-b and Figure S1.1-5). The  
 144 sizes are summarized in Table 1 along with the Au:Pd molar ratios estimated with ICP-  
 145 MS and XPS (Figure 1c). XPS spectra (Figure 1c) show a shift in Au 4f photoelectron peak  
 146 towards lower binding energies once Pd is present, which is a typical feature observed  
 147 for Au-Pd alloys [25]. The molar ratio of the Au<sub>9</sub>Pd estimated by XPS differs slightly  
 148 from the value obtained via ICPMS. For low Pd content the estimation of the molar ratio  
 149 with XPS is less accurate owing to direct overlap between Pd(3d) and Au(4d) peaks.

150 **Table 1 Particle size and Au:Pd molar ratios estimated via ICP-MS and XPS of the prepared catalysts.**

	N of particle	median / nm	st. dev.	Au:Pd ratio ICPMS	Au:Pd ratio XPS
<b>Au</b>	298	4.3	±1.3	100:0	100:0
<b>Au<sub>9</sub>Pd</b>	362	2.7	±1.0	91:9	98:2
<b>Au<sub>3</sub>Pd</b>	322	3.5	±1.1	77:23	74:26
<b>AuPd</b>	251	4.1	±0.8	46:54	48:52
<b>AuPd<sub>3</sub></b>	285	3.7	±1.1	26:74	27:73
<b>Pd</b>	277	3.2	±1.2	0:100	0:100

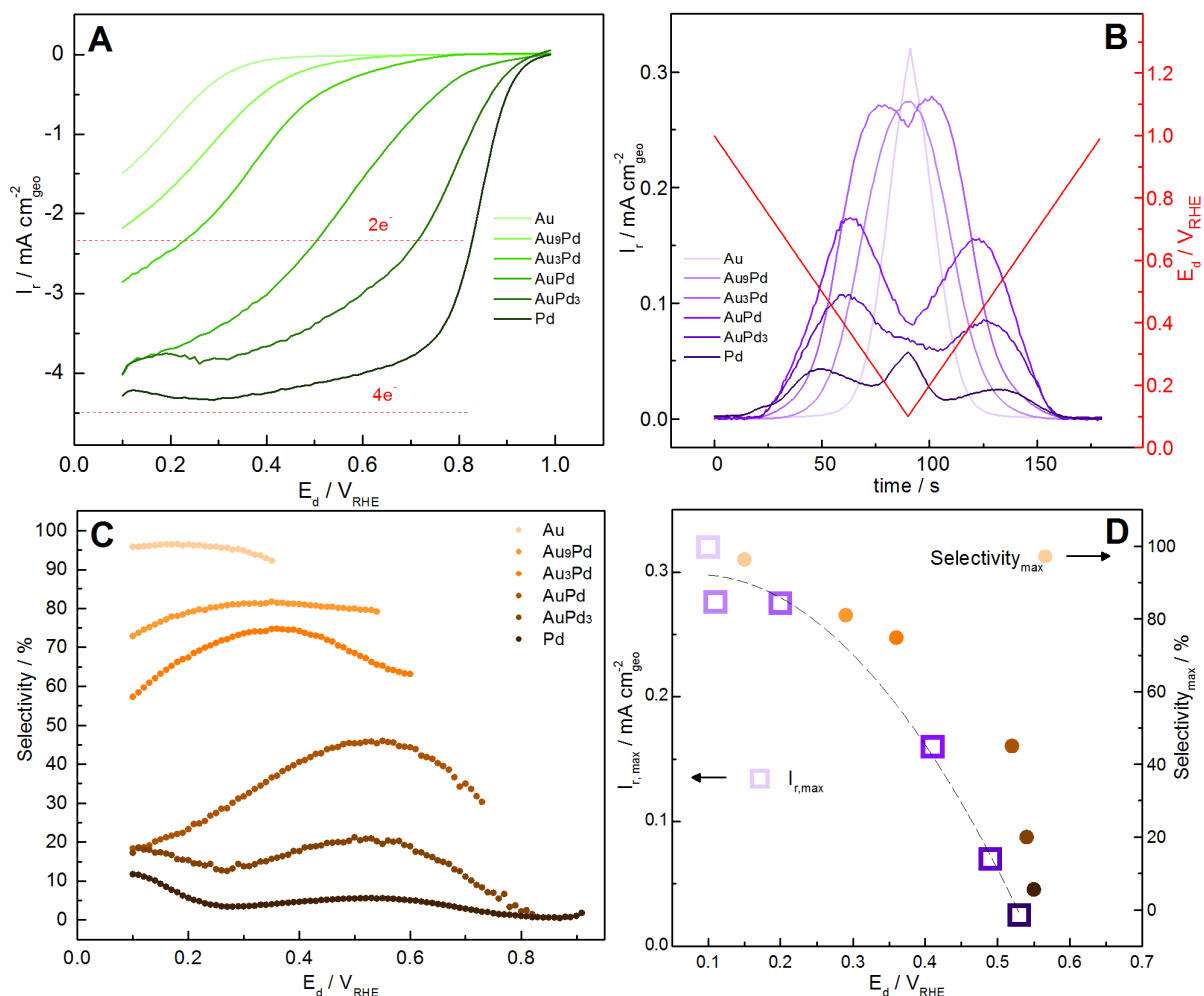

151

152 The shape of the initial Ar background cyclic voltammograms (CVs) (Figure 1d and as  
153 reference poly-Au and poly-Pd electrodes in Figure S2.1-2) are related to the surface  
154 state and composition. The upper potential limit (UPL) of  $1.6 V_{RHE}$  is chosen in order to  
155 measure the Au oxide (denoted as Au-O due to lack of information about stoichiometry)  
156 reduction peak which is only distinguishable with high UPLs [26]. Typical features of Au  
157 and Pd vary with the composition. Hydrogen under potential deposition ( $H_{UPD}$ ) is only  
158 present in samples with high Pd content (from 1:1 molar ratio Au:Pd onwards).  
159 Furthermore, two peaks in the  $H_{UPD}$  are observed for  $AuPd_3$  and Pd in accordance with  
160 previous literature [27]. Proceeding anodically, the onset potential for the Pd oxide (Pd-  
161 O is used as exact composition is not known) and Au-O formation are around  $0.7 V_{RHE}$   
162 and  $1.3 V_{RHE}$  respectively. The cathodic scan is dominated by two main features, namely  
163 Au-O and Pd-O reductions. For pure Pd and Au catalysts the maxima of the respective  
164 reduction peak were measured at  $0.6 V_{RHE}$  and  $1.1 V_{RHE}$ . The presence of one or two  
165 reduction peaks reflects the composition: (i) for low Pd content ( $Au_9Pd$ ) only the Au-O  
166 reduction is visible (as in [7]), whereas (ii) for high Pd content ( $AuPd_3$ ) only the Pd-O  
167 reduction is present (as in [28]); (iii) for intermediate compositions ( $Au_3Pd$  and  $AuPd$ ),  
168 instead, two peaks are observed. Interestingly, the Pd-O peak position shifts significantly  
169 when Pd is mixed to Au. Such a shift has been attributed to alloying [7, 22, 28] and was  
170 exploited by Rand and Woods to define the surface composition based on a linear  
171 dependence with the reduction potential [29]. However, this approach was shown to be  
172 limited only to high Pd content ( $> 40\%$ ) [28, 30] and for Au-Pd non-polarized to  $H_{UPD}$   
173 where H absorption might take place [28]. Even though quantification is difficult, the  
174 position and the associated charges are good indicators of surface composition changes.  
175 Note, that also potential cycling might cause minor changes in surface composition due  
176 to metal segregation [21].

### 177 **3.2 Oxygen Reduction Reaction (ORR)**

178 The ORR on Au-Pd nanoparticles is studied with the RRDE (calibration in Figures S3.1-2)  
179 with simultaneous  $H_2O_2$  monitoring at the ring during the ORR. From the detected  
180 currents, disc ( $I_d$ ) and ring ( $I_r$ ), the  $H_2O_2$  selectivity ( $S_{H_2O_2}$ ) is derived.

181

182 **Figure 2 RRDE results obtained for ORR on different Au-Pd catalyst compositions in O<sub>2</sub> saturated 0.1M HClO<sub>4</sub>.**  
 183 **Rotation: 900 rpm. Scan rate: 50 mV s<sup>-1</sup>. E<sub>r</sub>: 1.28 V<sub>RHE</sub>. The colors (green for I<sub>d</sub>, violet for I<sub>r</sub>, brown for S<sub>H<sub>2</sub>O<sub>2</sub>) are</sub>**  
 184 **graded with the change in composition. (a) Disc anodic polarization current (I<sub>d</sub>) (b) Ring current (I<sub>r</sub>) profiles**  
 185 **during one cycle [0.1-1.0] V<sub>RHE</sub>. (c) Calculated values of S<sub>H<sub>2</sub>O<sub>2</sub>. (d) S<sub>H<sub>2</sub>O<sub>2</sub> and I<sub>r</sub> maxima vs. disc potential.</sub></sub>**

186 The results are summarized in Figure 2 (Au and Pd polycrystals are reported in Figures  
 187 S4.1-4). The ORR data collected at the disc ( $I_d$  in Figure 2a) show at a glance, how the  
 188 composition significantly affects the ORR onset potentials: from 0.4 V<sub>RHE</sub> for Au it shifts  
 189 positively, until 0.9 V<sub>RHE</sub> for Pd. The theoretical diffusion limited currents (dashed lines  
 190 in Figure 2a) calculated from the Levich equation [31] suggest a mechanism change from  
 191 a 2 (dominant H<sub>2</sub>O<sub>2</sub> production) to a 4-electrons process with increasing Pd content.

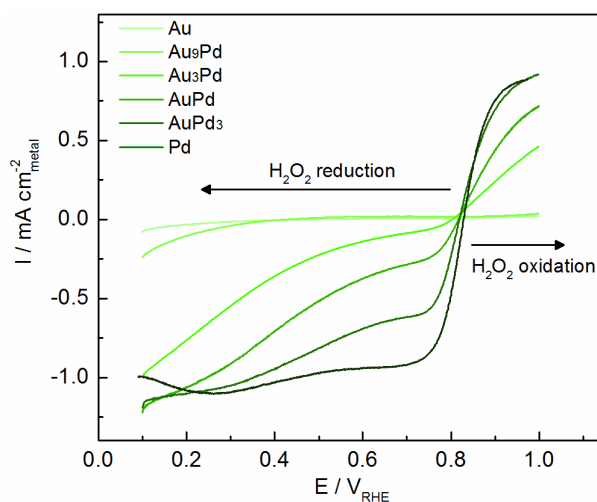

192 The presence of H<sub>2</sub>O<sub>2</sub> is confirmed by the  $I_r$  profiles (Figure 2b), corresponding to H<sub>2</sub>O<sub>2</sub>  
 193 oxidation ( $\text{H}_2\text{O}_2 \rightarrow \text{O}_2 + 2\text{H}^+ + 2\text{e}^-$ ). The total H<sub>2</sub>O<sub>2</sub> current ( $I_{\text{per}}$ ) can be estimated from  
 194 correcting  $I_r$  by the collection efficiency  $N$  and compared to  $I_d$  (Figure S4.5). As observed  
 195 from the  $I_d$  and the  $I_r$ , H<sub>2</sub>O<sub>2</sub> production is considerably influenced by composition. In  
 196 particular, the highest  $I_r$  is measured for pure Au ( $\sim 0.32 \text{ mA cm}_{\text{geo}}^{-2}$  @ 0.1 V<sub>RHE</sub>) and the  
 197 lowest for Pd ( $< 0.05 \text{ mA cm}_{\text{geo}}^{-2}$ ). Interestingly, for low Pd contents (Au, Au<sub>9</sub>Pd, Au<sub>3</sub>Pd)  
 198 the onset potentials at the ring and the disc coincide, while for the remaining  
 199 composition (AuPd, AuPd<sub>3</sub>, Pd) the  $I_r$  onset potential remains constant at a value close to  
 200 the standard potential (0.69 V). Note that, in a 2-electron process the peak of the volcano

201 plot coincides with the standard potential. Thus, a catalyst for the  $\text{H}_2\text{O}_2$  production can  
202 have zero overpotential [32]. Tentatively, the lack of overpotential can explain the fact  
203 that the  $I_r$  onset potential for active catalyst coincide. Interestingly, for  $\text{AuPd}_3$  and Pd an  
204  $I_r$  peak is observed at low potential ( $<0.2-0.3 V_{\text{RHE}}$ ) where Pd is covered with hydrogen.  
205 This is well known also for Pt-based catalysts [33].

206 As  $I_r$ , the  $S_{\text{H}_2\text{O}_2}$  (Figure 2c) decreases with Pd content from a  $S_{\text{H}_2\text{O}_2, \text{max}}$  of  $\sim 95\%$  to less  
207 than 10% for pure Au and Pd respectively. As also observed elsewhere, both  $S_{\text{H}_2\text{O}_2}$  and  $I_r$   
208 exhibit a maximum [7, 8, 13]. Tentatively, this can be attributed to a mechanism change  
209 with increasing overpotential. As for the onset-potential also the maxima of  $I_r$  and  $S_{\text{H}_2\text{O}_2}$   
210 are shifting similarly with the composition (Figure 2d). The high  $S_{\text{H}_2\text{O}_2}$  of Au is confirmed  
211 also with poly-Au (see Figure S4.4). Both show similar onset potentials and  $S_{\text{H}_2\text{O}_2}$  around  
212 95-98%. In a recent publication on carbon supported Au-Pd catalysts, Jirkovsky *et al.*  
213 observed a  $S_{\text{H}_2\text{O}_2}$  enhancement for low Pd concentration ( $<15\%$ ) with a maximum for 8%  
214 Pd [7], whose  $S_{\text{H}_2\text{O}_2}$  approached 95%. This was attributed to geometric effect due the  
215 presence of single Pd atoms surrounded by Au. Our  $\text{Au}_9\text{Pd}$  does not show improvement  
216 in terms of  $S_{\text{H}_2\text{O}_2}$  compared to the pure Au sample, whose  $S_{\text{H}_2\text{O}_2}$  is already approaching  
217 95%. The influence of the support and of isolated Pd needs to be further addressed in  
218 future studies. Indeed, first principles calculation suggests an influence on  $S_{\text{H}_2\text{O}_2}$  due to  
219 geometric effect [34], that could correspond to a shift in onset potential while  
220 maintaining a high  $S_{\text{H}_2\text{O}_2}$ .

### 221 3.3 Peroxide Reduction and Oxidation Reaction (PROR)

222  
223 **Figure 3 Anodic sweep of the PROR on various Au-Pd catalyst compositions in Ar saturated 0.1M  $\text{HClO}_4$  +**  
224 **10mM  $\text{H}_2\text{O}_2$ . Rotation: 900 rpm. Scan rate : 50  $\text{mV s}^{-1}$ .**

225 Once produced,  $\text{H}_2\text{O}_2$  can “degrade” through: (i) electrochemical peroxide reduction  
226 (PRR) ( $\text{H}_2\text{O}_2 + 2\text{e}^- + 2\text{H}^+ \rightarrow 2\text{H}_2\text{O}$ ), (ii) electrochemical peroxide oxidation (POR)  
227 ( $\text{H}_2\text{O}_2 \rightarrow \text{O}_2 + 2\text{e}^- + 2\text{H}^+$ ) and (iii) chemical disproportionation ( $2\text{H}_2\text{O}_2 \rightarrow 2\text{H}_2\text{O} + \text{O}_2$ ). The  
228 latter is influenced by the reaction environment, whereas the others are mainly related  
229 to the catalyst surface and presence of impurities [35, 36]. It is therefore of utmost  
230 importance to answer the question of whether the produced  $\text{H}_2\text{O}_2$  would be further

231 reduced in a fuel cell at operational potentials, dominated by PRR. PROR was studied in  
 232 Ar-saturated 0.1M HClO<sub>4</sub> containing 10 mM of H<sub>2</sub>O<sub>2</sub> (Figure 3). Interestingly, the  
 233 polarization curves match around 0.8 V<sub>RHE</sub>. At such potential, the dominating reaction  
 234 (PRR to POR) changes with the surface state (reduced to oxidized), as observed for poly-  
 235 Pt [36]. The Pd oxidation onset is ~0.7 V<sub>RHE</sub>, which is indeed when the PRR current starts  
 236 to decrease (see also poly-Pd in Figure S5.1). Inactive metals for ORR are also less active  
 237 for PRR: an increase in Au content corresponds to a proportional decrease in both ORR  
 238 (Figure 2) and PRR (Figure 3). This trend is also confirmed by previous literature on co-  
 239 electrodeposited Au-Pd [22, 37]. Already at 10% Pd content an undesired (even though  
 240 limited) increase in the H<sub>2</sub>O<sub>2</sub> reduction current was observed. As Au is selective and not  
 241 active for the PRR, it can be indicated as the best candidate for applications that require  
 242 high S<sub>H2O2</sub>.

### 243 3.4 Potentiostatic H<sub>2</sub>O<sub>2</sub> production

244

245 **Figure 4 Measured  $I_d$  (a) and  $I_r$  (b) during 2 min potentiostatic experiment in O<sub>2</sub> saturated 0.1M HClO<sub>4</sub>.**  
 246 **Rotation: 900 rpm.  $E_d$  corresponds to the potential of  $I_{r,max}$  (see Table 2).  $E_r$ : 1.28 V<sub>RHE</sub>.**

247 To finally bridge the gap between possible “real application” and our fundamental  
 248 studies we need to understand how the catalysts behave during demanding continuous  
 249 H<sub>2</sub>O<sub>2</sub> production. RRDE data (Figure 4 and Figure S6.1) during 2 min potentiostatic  
 250 condition (potential of  $I_{r,max}$  for each composition) confirms the activity and S<sub>H2O2</sub> trend  
 251 observed in the previous sections. Interestingly, the  $I_r$  (and thus S<sub>H2O2</sub>) slightly increases  
 252 with time for Pd rich catalysts (AuPd<sub>3</sub>, Pd). This is even more evident during the 30  
 253 minutes measurements (see Figure S6.1) and can be tentatively attributed to the  
 254 presence of either impurities or spectator species that initially poison active sites  
 255 favoring the H<sub>2</sub>O<sub>2</sub> production, as observed for Pt [38]. Such spectator species can be

256 easily removed with a simple CV [13]; indeed, the ORR behavior before and after the  
257 measurement is not affected (see Figure S6.2).

258 The productivity (Table 2) of the catalyst after 2 and 30 minutes is determined from the  
259 POR limiting current on Pt (see calibration in Figure S6.3). In line with the high  $S_{H_2O_2}$  and  
260 low PRR activity of Au, its productivity is the highest. Thus, the measurement on Au was  
261 extended to 1 and 2 h yielding 12.3 and 22.9 mol  $g_{metal}^{-1} cm^{-2}_{geo}$ . Increasing the Pd  
262 content, the  $S_{H_2O_2}$  decreases and PRR activity increases, resulting in a proportional  
263 productivity decrease. Despite the low productivity expected for 4-electron catalysts  
264 with low  $S_{H_2O_2}$  as Pd, it yields  $\sim 2.40$  mol  $g_{metal}^{-1} cm^{-2}_{geo}$  after 30 min. This can be again  
265 attributed to a poisoning of the active sites for complete reduction, favoring a 2-electron  
266 process.

267 **Table 2 H<sub>2</sub>O<sub>2</sub> productivity after 2 and 30 mins of measurement.**

	Potential hold (V <sub>RHE</sub> )	Productivity 2 min (mol $g_{metal}^{-1}$ $cm^{-2}_{geo}$ )	Productivity 30 min (mol $g_{metal}^{-1}$ $cm^{-2}_{geo}$ )
Au	0.10	0.46	6.79
Au <sub>9</sub> Pd	0.15	0.39	5.46
Au <sub>3</sub> Pd	0.25	0.40	5.87
AuPd	0.40	0.29	3.37
AuPd <sub>3</sub>	0.45	0.24	3.42
Pd	0.50	0.14	2.40

268

## 269 4 Conclusions

270 A set of Au-Pd nanocatalysts are synthesized as model catalysts to study the  
271 electrocatalytic behaviour for H<sub>2</sub>O<sub>2</sub> synthesis from fundamental perspectives and for  
272 continuous H<sub>2</sub>O<sub>2</sub> production.

273 The ORR and the PROR behavior are significantly affected by the composition: upon an  
274 increase in Au content we observe an increase in  $I_r$  and  $S_{H_2O_2}$ , whereas the onset is  
275 shifting to lower potentials. The  $S_{H_2O_2}$  of Au is the highest (95%) at the price of low  
276 activity. Previous theoretical studies as well as experimental works suggest that  
277 geometrical effects (triggered by the presence of atomically dispersed Pd in Au) might  
278 enhance the activity whereas maintaining high  $S_{H_2O_2}$ , which are however not observed in  
279 this work. For Au<sub>9</sub>Pd and Au<sub>3</sub>Pd, the activity is indeed higher (i.e. H<sub>2</sub>O<sub>2</sub> formation onset  
280 potential already close to nominal for Au<sub>3</sub>Pd), but the  $S_{H_2O_2}$  decreases while remaining  
281 relatively high (between 60 and 80%). With an eye on applications, these compositions  
282 might still be interesting where a compromise between  $S_{H_2O_2}$  and energy output is  
283 allowed, as the typical end-user requires H<sub>2</sub>O<sub>2</sub> concentration in the range 2-8 wt%. On  
284 the other hand, if high H<sub>2</sub>O<sub>2</sub> concentration and high  $S_{H_2O_2}$  is required, pure Au would  
285 potentially be the catalyst of choice, as the productivity during a potentiostatic  
286 measurement indicates (highest productivity that steadily increases up to 2h).

287 Our observations on a spectrum of compositions between elements with contrasting O<sub>2</sub>  
288 adsorption energy can be extended to other alloys with similar characteristic. The

289 fundamental studies help to forecast the ORR behavior and reaction selectivity for  
290 potential applications. Furthermore, future investigations on fuel cells, the stability of  
291 catalysts, as well as on the effect of support are of particular importance to understand  
292 how these catalysts will perform in real applications.
